

# Theory of Practical Graph Algorithms - Part II

Laurent Viennot - Mauro Sozio

MPRI - [laurent.viennot@inria.fr](mailto:laurent.viennot@inria.fr) - Inria (rue Barrault)

## Part II : Outline

- Diameter/radius computation - Hardness in P (1 lecture)
- Shortest path queries - Distance labeling (1.5 lectures)
- Temporal graphs (1 lecture)
- Graph neural networks (0.5 lecture)

# Diameter/radius computation

Hardness of diameter computation and fine-grained complexity

Practical algorithms and why they work

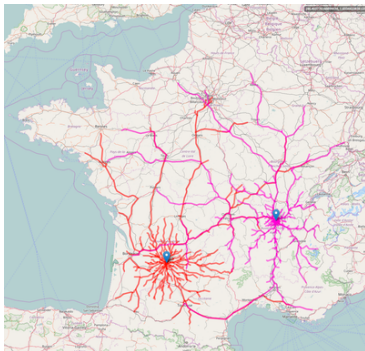

# Shortest path queries

A line of practical algorithms

Some theoretical insight in their efficiency

Links with the theory of distance oracles

# Temporal graphs

A hierarchy of models

Classical graph problems revisited

# Graph neural networks

Expressive power and isomorphism tests

(under construction)

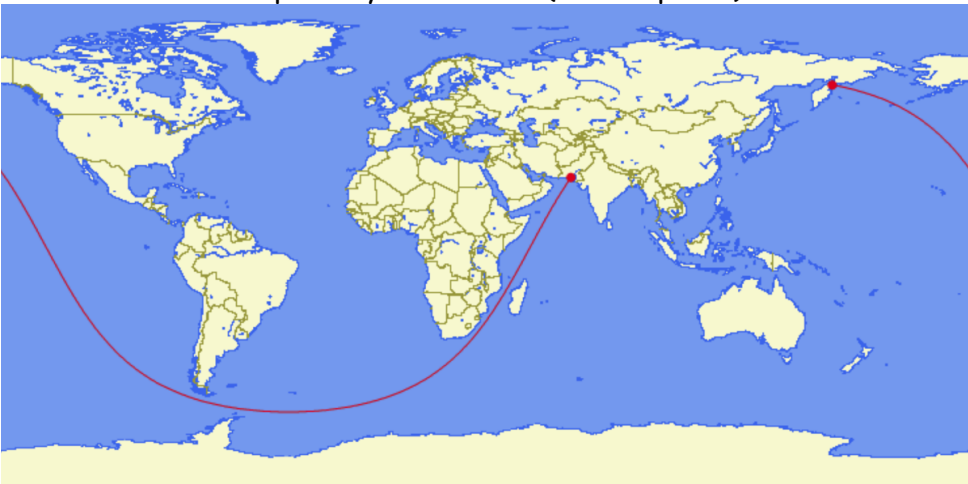

Diameter

How big is the world?

# Longest straight line on water

Reddit user kepleronlyknows 2012 (in r/MapPorn) :

# Longest straight line on water

[Chabukswar, Mukherjee 2018] :

"The problem was approached as a purely mathematical exercise. The authors do not recommend sailing or driving along the found paths."

# Longest straight line on land

[Chabukswar, Mukherjee 2018]:

"The problem was approached as a purely mathematical exercise. The authors do not recommend sailing or driving along the found paths."

# World longest road trips

<http://gang.inria.fr/road/>

# Graph notations

A (weighted directed) **graph  $G$**  is defined by :

a set  $V(G)$  of **nodes/vertices** (or simply  $V$ ),

a set  $E(G)$  of **arcs/edges** (or simply  $E$ ),

a **length function**  $\ell : E \rightarrow \mathbb{R}^+ : \ell(uv)$  is the **length/weight** of arc  $uv \in E$  (default is 1).

**Size** :  $n(G) = |V(G)|$  (or simply  **$n$** ) is the **number of nodes**, and  $m(G) = |E(G)|$  (or simply  **$m$** ) is the **number of edes**.

$G$  is **undirected** when  $uv \in E \iff vu \in E$ .

$G$  is **unweighted** when  $\ell(uv) = 1$  for all  $uv \in E$ .

A  **$uv$ -path** with  **$k$  hops** is a sequence of arcs

$P = x_0x_1, \dots, x_{k-1}x_k$  with  $x_0 = u$  and  $x_k = v$ , its **length is**

$$\ell(P) = \sum_{i=1}^k \ell(x_{i-1}x_k).$$

The **distance**  $d_G(u, v)$  (or simply  $d(u, v)$ ) from  $u$  to  $v$  is the minimum length of a  $uv$ -path.

# Graph parameters

**Practical graphs** : <https://networkrepository.com/>

**General shape** :

size, connectivity, average distance (**Milgram exp.**),...

Six degrees of separation

**Node measures** :

degree, pagerank, xx-centrality,...

Periodic Table of Network Centrality [Schoch 15]

# Computing graph parameters

**Average distance** (degree of separation) :

- All pairs distances :  $O(nm)$  or  $O(n^\omega \log n)$  unweighted [Alon et al 91; Seidel 95] or  $O(W^{(\omega-1)/2} n^{(3+\omega)/2} \log n)$  [Galil Margalit 97] (with  $O(n^\omega)$  matrix multiplication)
- Approximation with sampling and empirical average.

**Centrality measures** : what nodes are "central" ?

- **betweenness**  $b(v) = \sum_{s,t} \frac{\sigma_{st}(v)}{\sigma_{st}}$  [Freeman 77; Anthonisse 71]  
 $\sigma_{st}$  : number of  $st$ -shortest paths,  $\sigma_{st}(v)$  : that pass through  $v$
- **stress**  $s(v) = \sum_{s,t} \sigma_{st}(v)$  [Shimbel 53]
- **(harmonic) closeness**  $c(v) = \sum_t \frac{1}{d(v,t)}$  [Marchiori, Latora 2000]
- **graph closeness**  $g(v) = \frac{1}{\max_t d(v,t)}$  [Hage Harary 95]
- **eccentricity**  $e(v) = \max_t d(v,t)$  [Hage Harary 95]
- Often  $O(nm)$  (for all  $v$ ) [Brandes 01]

**Diameter** : maximum distance

- Diameter  $\text{diam}(\mathcal{G}) = \max_v e(v)$
- Radius  $\text{rad}(\mathcal{G}) = \min_v e(v)$

# Diameter computation

**Naive algorithm** : compute  $e(v)$  through a BFS for all  $v \in V$ .

**Complexity** :  $\Theta(nm) = O(m^2)$ .

Can we do better?

Should we search for  $O(m^c)$ -time with  $c < 2$ ?

# The $O(nm)$ barrier

**Theorem** [Roditty Vassilevska-Williams 13]: There is no  $O(m^{2-\epsilon})$ -time diameter algorithm under SETH (for any  $\epsilon > 0$ ).

**Proof idea**: reduce SAT (satisfiability of a CNF formula with  $N$  variables) to Diameter  $> 2$ .

**Definition**:

$s_k = \inf \left\{ \delta \mid k\text{-SAT has a } O(2^{\delta N})\text{-time algorithm} \right\}$

**Exponential time hypothesis (ETH)** [Impagliazzo Paturi 01]:

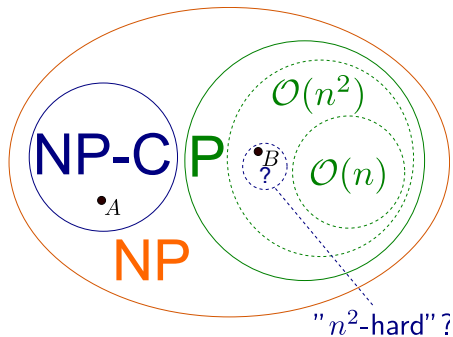

$s_3 > 0$ . (ETH  $\Rightarrow$  P  $\neq$  NP)

**Strong ETH (SETH)** (informal):  $\forall \epsilon > 0$ , there is no  $O(2^{(1-\epsilon)N})$ -time algorithm for SAT.

**Formal SETH**:  $\lim_{k \rightarrow \infty} s_k = 1$ , i.e. for all  $\epsilon > 0$ , there exists  $k$  s.t.  $k$ -SAT cannot be solved in  $O(2^{(1-\epsilon)N})$ -time.

**Known upper bounds**: 3-SAT in  $O(2^{0.39N})$  and  $k$ -SAT in  $O(2^{(1-c/k)N})$  for some  $c > 0$ . [PaturiPSZ 05, Hertli 14]

# Hardness in P : fine-grained complexity

## Hardness in P : fine-grained complexity

What is the true  $c$  in  $O(n^c)$  algorithms?

**Quasi-linear reduction** :  $P \leq_c Q$  if any  $O(n^{c-\epsilon})$  algorithm for  $Q$  can be turned into an  $O(n^{c-\epsilon'})$  algorithm for  $P$ .

Exemple :  $OV=DisjSet \leq_2$  Diameter as the existence of two disjoint sets in a collection of  $n$  sets in a universe of size  $\tilde{O}(1)$  can be reduced to a diameter problem on  $\tilde{O}(n)$  nodes in  $\tilde{O}(n)$  time.  
( $\tilde{O}(\cdot)$  hide poly-log factors.)

**Exercise** : prove  $HitSet \leq_2$  Radius.

# Hardness in P : fine-grained complexity

## Tentative hard problems :

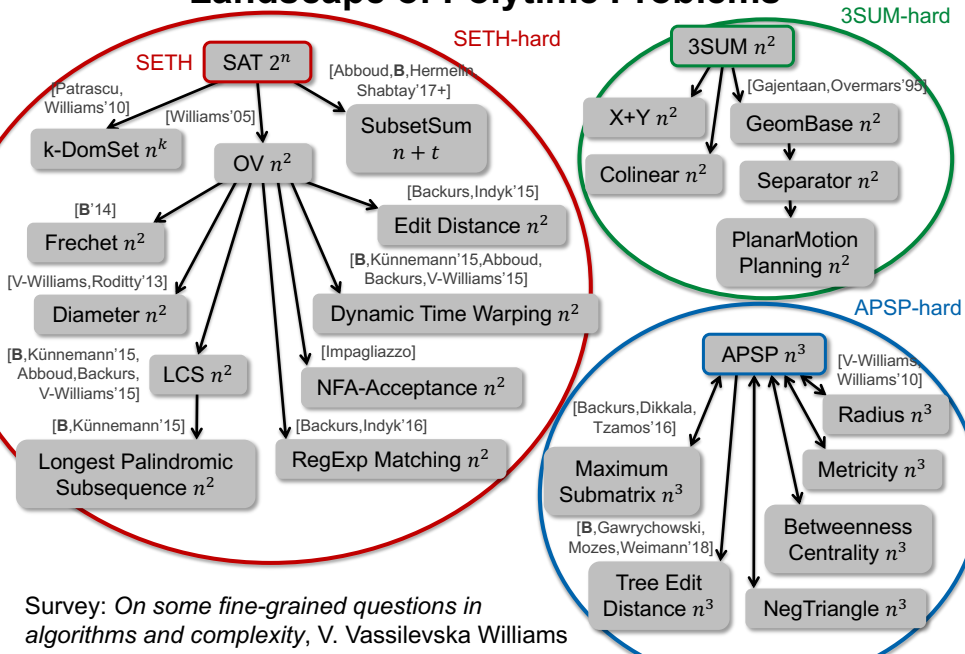

- HitSet for  $O(n^2)$  : given two collections  $A, B$ , does a set of  $A$  hits all sets of  $B$ ?
- 3SUM for  $O(n^2)$  : given  $n$  integers, do 3 of them sum to 0?
- All Pairs Shortest Paths (APSP) for  $O(nm)$ .
- $d$ -dim OV for  $O(n^2)$  ( $d = c \log n$ ) : given two sets  $A, B$  of binary vectors of dimension  $d$ , does there exist  $a \in A$  and  $b \in B$  such that  $a$  and  $b$  are orthogonal.
- $k$ -OV for  $O(n^k)$  : given  $n$  vectors of dimension  $d$ , does there exist  $k$  of them with product zero?

## Conjectures :

- HitSet hypothesis : HitSet requires time  $n^{2-o(1)}$ .
- OVH : OV requires time  $n^{2-o(1)}$ .
- $k$ -OVH :  $k$ -OV requires time  $n^{k-o(1)}$ .

Exercise : prove HitSetHyp  $\Rightarrow$  OVH.

# Landscape of Polytime Problems

Survey: *On some fine-grained questions in algorithms and complexity*, V. Vassilevska Williams

# Hardness of approximation

Diameter can be 2-approximated in  $O(m)$ -time.

$(2 - 1/k - \delta)$ -approximation requires time  $m^{1+1/(k-1)-o(1)}$  under SETH. [Dalirrooyfard, Li, Williams 21]

There exists a 3/2-approximation in  $\tilde{O}(m^{3/2})$ -time. [Chechik LRSTW 14]

No  $(3/2 - \delta)$ -approximation in  $m^{2-\epsilon}$ -time under SETH. [Roditty, Williams 13]

No 3/2-approximation (even  $5/3 - \delta$ -approx) in  $m^{3/2-\epsilon}$ -time under SETH. [Backurs RSWW 18]

## Practical diameter

**Diameter** of Facebook graph is **141** in 2011 [Backstrom et al 12] (720m nodes, 69g edges).

**iFUB** algorithm [Crescenzi et al 10] : carefully choose BFS sources and improve lower/upper bounds on  $\text{diam}(G)$  (17 BFSs for Facebook2011).

# iFUB (iterative Fringe Upper Bound)

Given a BFS from  $s$ ,  $F_j$  are the nodes at distance  $j$  from  $s$ .

**Lemma** : If a node  $x$  in  $F_i$  with  $i \leq j$  has eccentricity  $e(x) > 2j$ , then some node  $y \in F_k$  with  $k > j$  has eccentricity  $e(y) \geq e(x) > 2j$ .

**Corollary** : If  $D_L := \max_{y \in F_k, k > j} e(y)$ ,  
 $D_L \leq \text{diam}(G) \leq \max(2j, D_L)$ .

**Algorithm** : Scan nodes in  $F_j$  for  $j = e(s), \dots, 1$  and update  $D_L := \max_{y \in F_j} e(y)$  until  $2j \leq D_L$ .

**Analysis** : a BFS for each node in  $F_k$  with  $k > \text{diam}(G)/2$ .

**Exercise** : choice of  $s$ ?

**Exercise** : hard graph for iFub?

**Efficient** in random power-law graphs [Borassi et al 17].

# Heuristic diameter

**Two sweeps** : Given  $G$  and  $u \in V(G)$ , do  $\text{BFS}(u)$  and  $\text{BFS}(v)$  where  $v = A(u)$  is the **antipode** of  $u$  (last visited node in  $\text{BFS}(u)$ ), return  $d(v, A(v))$ .

**Theorem** : correct if  $G$  is a tree [Handler 73], and  $+1$  approximation if  $G$  is chordal [Corneil et al 03].

Chordal : no induced cycle of length  $> 3$ .

Often within  $+1$  in practice.

Tentative **center** : the middle node in-between  $v$  and  $A(v)$ .  
Center : a node with minimum eccentricity.

# Bound eccentricities [Takes, Kusters 2011] (revisited)

A BFS from  $s$  provides **bounds on eccentricities** :

$$\forall u, d(s, u) \leq e(u) \leq d(s, u) + e(s)$$

$X := \emptyset$ ; scanned nodes

Maintain  $e_L(u) := \max_{s \in X} d(u, s)$

and  $e^U(u) := \min_{s \in X} d(u, s) + e(s)$  for all  $u \in V(G)$ .

**While**  $\min_{u \in V} e_L(u)$  or  $\max_{u \in V} e^U(u)$  is not tight **do**

    Select  $u \in V$  s.t.  $e_L(u)$  is **minimal** and add it to  $X$ .

    Select  $u \in V$  s.t.  $e^U(u)$  is **maximal** and add it to  $X$ .

Last generation : exact sum-sweep [Borassi et al. 2017].

# Why such algorithms work?

What **graph property** enables fast diameter computation?

iFUB :

- $\text{diam}(G)$  close to  $2 \text{rad}(G)$ ,
- few far nodes.

Takes and Koster's algorithm?

Practical graphs have **small certificates**.

# Small certificate implies $O(n^{2-\epsilon})$ algorithm

$X$  is a diameter certificate if

$$\forall u, \min_{x \in X} d(u, x) + \text{ecc}(x) \leq \text{diam}(G)$$

Certificate of size  $\ell(n)$  implies a  $O(m\ell(n))$  non-deterministic algorithm.

**Theorem** [Dragan et al. 2024] For any class of graphs with diameter certificates of size  $\ell(n)$ , there exists a randomized algorithm for diameter running in  $O(m\sqrt{\ell(n)n} \log^{3/2} n)$  time.

# Diameter parameterized by certificate size

$X$  is a **diameter certificate** if

$$\forall u, \min_{x \in X} d(u, x) + \text{ecc}(x) \leq \text{diam}(G)$$

**Equivalently** :  $V \subseteq \cup_{x \in X} B[x, \text{diam}(G) - \text{ecc}(x)]$

where  $B[x, r] = \{u : d(u, x) \leq r\}$  (ball of radius  $r$  centered at  $x$ ).

$X$  corresponds to a covering with certain balls!

# Diameter parameterized by certificate size

**Main idea** : binary search the **value D** of the diameter, while solving **set cover** with  $\{B[y, D - ecc(y)] : y \in V\}$ .

**Problem** : The set-cover instance may have size  $\Omega(n^2)$ .

**Workaround** : Greedy set-cover with an implicit representation through set/containment queries [Sen, Muralidhara 2010].

**Problem** : Still requires to know  $ecc(y)$  for all  $y$ .

**Workaround** :

- Find for all  $y$ , an estimate  $r(y) \leq ecc(y)$  s.t.

$|B[y, r(y)]| \geq (1 - \epsilon)n$  using random sampling ( $O(\epsilon^{-1} \log n)$  BFSs):

- run **greedy set-cover** using  $\{B[y, D - r(y)] : y \in V\}$  and selecting at most  $q = \ell(n) \log n$  balls with centers  $x_1, \dots, x_q$ ;

- $\forall i$ , check  $ecc(v) \leq D$  for all  $v \in V \setminus B[y, D - r(x_i)]$  ( $qn$  queries).

Plugging  $\epsilon = \frac{1}{\sqrt{n\ell(n) \log n}}$  yields the result.

## Open questions

Certificates for diameter approximation?

Certificates for other hard problems in P?

# Few far nodes [Borassi, Crescenzi, Trevisan 2017]

Random power law graph :

- sequence of degrees s.t.  $\Theta(n/d^\beta)$  nodes with degree  $d$ ,
- create edges according to the **configuration model**.

For  $2 < \beta < 3$ ,

- $D = (1 + o(1))c(\beta) \log n$ ,
- $\text{dist}_{\text{avg}} = (2 + o(1)) \log_{1/(\beta-1)} \log n$ ,
- nb vertices at  $\text{dist} \geq D/2$  from a random  $v$  is at most  $n^{O(\epsilon)}$  for  $n > n_\beta$  ( $\epsilon = 0.2$  experimentally).

# Diameter certificate [Dragan et al. 2018]

For any  $L, U \subseteq V(G)$  and  $u \in V(G)$  :

$$e_L(u) \leq e(u) \leq e^U(u), \text{ where } \begin{cases} e^U(u) = \min_{x \in U} d(u, x) + e(x) \\ e_L(u) = \max_{x \in L} d(u, x) \end{cases}$$

$L$  is a **radius certificate** if  $e_L(u) \geq \text{rad}(G)$  for all  $u \in V$ .

For all  $u \in V$ ,  $\exists x \in L$  such that  $d(x, u) \geq \text{rad}(G)$  :

$L$  is a **covering** with  $\{\overline{B}(u, \text{rad}(G)) : u \in V\}$ .

$U$  is a **diameter certificate** if  $e^U(u) \leq \text{diam}(G)$  for all  $u \in V$ .

For all  $u \in V$ ,  $\exists x \in U$ , such that  $d(x, u) \leq \text{diam}(G) - e(x)$  :

$U$  is a **covering** with  $\{B[u, \text{diam}(G) - e(u)] : u \in V\}$ .

# Example

$D$  : certificate for  $\text{diam}(G) = 4q - 2$ ,  $R$  for  $\text{rad}(G) = 2q + 1$

**Exercise** : what about a path?, a grid?

# Diameter computation as a primal-dual alg. [Dragan et al. 2018]

$U := \emptyset; K := \emptyset$

**Do**

Select  $u$  such that  $e^U(u)$  is **maximal**.

$K := K \cup \{u\}$

Select  $x$  such that  $d(u, x) + e(x) = e(u)$ . E.g.  $x := u$ .

$U := U \cup \{x\}$

**while**  $\max_{u \in K} e(u) < \max_{u \in V} e^U(u)$

**Return**  $e(b)$ ,  $b$  and  $U$  where  $e(b) = \max_{u \in K} e(u)$ .

$U$  is a covering with  $\{B[u, \text{diam}(\mathcal{G}) - e(u)] : u \in V\}$ .

$K$  is a packing for  $\{B(u, \frac{1}{3}(\text{diam}(\mathcal{G}) - e(u))) : u \in V\}$ .

Approximation ratio  $\frac{\pi_{1/3}}{\pi_{[1]}}$ ,  $O(\pi_{1/3})$  BFS.

Most practical graphs have diameter certificate  $|U| < 30$ .

## Radius computation : iterate two-sweeps as a primal-dual alg. [Dragan et al. 2018]

$L := \emptyset; K := \emptyset$

**Do**

Select  $u \in V$  such that  $e_L(u)$  is minimal.

Compute distances from  $u$  (BFS from  $u$ ).

$a := \operatorname{argmax}_{v \in V} (d(u, v), \pi(v))$  /\* Antipode of  $u$ . \*/

$K := K \cup \{u\}$

$L := L \cup \{a\}$  (BFS from  $a$ )

**while**  $\min_{u \in V} e_L(u) < \min_{u \in K} e(u)$ .

**Return**  $e(c)$ ,  $c$  and  $L$  where  $c = \operatorname{argmin}_{u \in K} e(u)$ .

$\operatorname{rad}(G) = \min_{u \in V} e(u) \geq \min_{u \in V} e_L(u)$  and  $\min_{u \in K} e(u) \geq \operatorname{rad}(G)$

$K$  is a packing for  $\{\operatorname{Antipode}_r^{-1}(u) : u \in V\}$ .

$O(|\operatorname{Antipode}_r(V)|)$  BFSs : 2 per round (from  $u$  and  $a$ ).

Most practical graphs have  $< 40$  antipodes and radius certificate with  $|L| \leq 5$ .

# Best radius algorithm using one-to-all distances queries

One-to-all distances algorithm :

- query distances from a node,
- use triangle inequality.

**Theorem** [Dragan et al. 2018] : If a one-to-all distances algorithm queries only  $k$  nodes to obtain the radius of a graph  $G$ , then  $G$  has a lower certificate of  $2k$  nodes.
