Abstract—We present a refinement of the Calculus of Inductive Constructions in which one can easily define a notion of relational parametricity. It provides a new way to automate proofs in an interactive theorem prover like Coq.

I. INTRODUCTION

The Calculus of Inductive Constructions (CIC in short) extends the Calculus of Constructions with inductively defined types. It is the underlying formal language of the Coq interactive theorem prover [1].

In the original presentation, CIC had three kinds of sorts: the impredicative sort of propositions Prop, the impredicative sort of basic informative types Set, and the hierarchy of universes Type0, Type1, Type2, … This presentation was not compatible with the possibility to add axioms in the system, since it could lead to inconsistencies [2]. Nowadays, there is no impredicative sort of relational parametricity in which the relations’ codomains is the maximum level of the domain and the codomain: A, B, P, Q, F := x | s | ∀x : A.B | λx : A.B | (A.B) | I | case_t(A, Q, P, F) | c | fix(x : A.B)

where s ranges over the set {Prop} ∪ {Set_i, Type_{i+1} | i ∈ N} of sorts and x ranges over the set of variables. We write Indp(I : A, c : C) to state that I is a well-formed inductive definition typed with p parameters, of arity A, with k constructors c1, …, ck of respective types C1, …, Ck.

A context Γ is a list of pairs x : A and the typing rules are the rules of CIC (one can refer to [1] for the complete set of rules), except to type sorts and dependent products. As for CIC, typing fixpoints (for fix) and elimination rules (for case) is subject to restrictions to ensure coherence. We present only the rules which are specific to our type system. Here are the three typing rules to type sorts:

Γ ⊢ Prop : Type 1
Γ ⊢ Set_i : Type_{i+1}
Γ ⊢ Type_i : Type_{i+1}

The following three typing rules tell which products are authorized in the system. The level of the product is the maximum level of the domain and the codomain:

Γ ⊢ ∀x : A.B : s_{max(i,j)}
(r, s) ∈ {Type, Set}

Quantifying over propositions does not rise the level of the product:

Γ ⊢ A : Prop
Γ ⊢ h : A : Prop
s ∈ {Type, Set}

And the sort Prop is impredicative, it means that products in Prop may be built by quantifying over objects whose types inhabit any sort:

Γ ⊢ A : s
Γ ⊢ A : Prop
s ∈ {Type, Set, Prop}

Finally, as in CIC, the system comes with subtyping rules based on the following inclusion of sorts (where i < j):

Prop := Set_1, Set_i := Set_j, Type_i := Type_j

One should note that CICref easily embeds into CIC by mapping any Set_i and Type_i onto the Type_i of CIC. The coherence of CIC thus implies the coherence of CICref.

III. PARAMETRICITY

We can define a notion of relational parametricity for CICref.
\[ \Theta_I(\overrightarrow{Q}^p, T, \overrightarrow{F}^n) = \lambda x : A (x' : A') (x_R : [A] x x') (a : I \overrightarrow{Q}^p \overrightarrow{x}^n) (a' : I \overrightarrow{Q}^p \overrightarrow{x'}^n) (a_R : [I] \overrightarrow{Q} Q [\overrightarrow{Q}] x x' x_R a a'). \]

\[ [T] x x' x_R a a'_R (\text{case}_I (a, \overrightarrow{Q}^p, T, \overrightarrow{F}^n)) (\text{case}_I (a', \overrightarrow{Q}^p, T', \overrightarrow{F}^n)) \]

Fig. 1. Relation parametricity for inductive types

**Definition 1** (Parametricity relation). For any inductive \( \text{Ind}^p (I : A, c : C) \), we define a fresh inductive symbol \( [I] \) and a family \( \{ [c_i] \}_{i=1 \ldots k} \) of fresh constructor names.

The parametricity translation \( \Theta \) is defined by induction on the structure of terms and contexts:

- \( \Theta (\emptyset) = \emptyset \)
- \( \Theta ([\Gamma, x : A]) = [\Gamma], x : A, x' : A', x_R : [A] x x' \)
- \( \Theta (s) = \lambda (x : s)(x' : s), x \to x' \to s \)
- \( \Theta (x) = x_R \)
- \( \Theta (\forall x : A.B) = \lambda (f : \forall x : A.B) (f' : \forall x' : A'.B') \).
- \( \forall (x : A)(x' : A')(x_R : [A] x x'). \)
- \( \Theta (B) (f x) (f' x') \)
- \( \Theta (\lambda x : A.B) = \lambda (x : A)(x' : A')(x_R : [A] x x'). [B] \)
- \( \Theta ([A B B'] B) \)
- \( \Theta (\text{fix} (x : A).B) = (\text{fix} (x_R : [A] x x'). [B]) \)
- \( \Theta (\text{case}_I (M, \overrightarrow{Q}^p, T, \overrightarrow{F}^n)) = \text{case}_I ([M], \overrightarrow{Q} Q [\overrightarrow{Q}], [\overrightarrow{Q}]^p, \Theta_I (\overrightarrow{Q}^p, T, \overrightarrow{F}^n)) \)

where \( \text{Prop} = \text{Set} \), \( \text{Prop} = \text{Prop} \) and \( \text{Type}_i = \text{Type} \), and where \( A' \) denotes the term \( A \) in which we have replaced each variable \( x \) by a fresh variable \( x' \). The definition of \( \Theta_I \) is in Fig. 1.

What is new with respect to previous works is the fact that relations over objects of type \( \text{Prop} \) or \( \text{Set} \), have their codomain in \( \text{Prop} \) instead of higher universes. We also formally define parametricity for inductive types.

Unfortunately, in order to prove the abstraction theorem below, we need to restrict the strong elimination: we have to disallow the case destructions used to build objects whose types are of sort \( \text{Prop} \) when the destructed inductive definition is not small (small inductive definitions are inductive definitions which constructors only have arguments of type \( \text{Prop} \) or \( \text{Set} \), see [6]). We write \( \vdash_s \) for the derivability where strong elimination is authorized only over small inductive definitions.

**Theorem 1** (Abstraction theorem). If \( \Gamma \vdash_s A : B \) then \( [\Gamma] \vdash_s A : B, [\Gamma] \vdash_s A' : B', \) and \( [\Gamma] \vdash_s A : [B] A A' \).

**IV. APPLICATIONS**

A lot of so-called “free theorems” are consequences of the abstraction theorem and our framework is expressive enough to implement most examples that can be found in the literature (see for instance [4], [7]).

Here we propose a new example inspired by François Garillot’s thesis [8], in which he remarks that polymorphic functions operating on groups can only compose elements using the laws given by the group’s structure, and thus cannot create new elements.

In our system, we may actually use parametricity theory to translate this uniformity property. We take an arbitrary group structure \( H \) defined by its carrier \( \alpha : \text{Set}_0 \), a unit element, a composition law, an inverse and the standard axioms stating that \( H \) is a group. We define \( \text{fingrp} \) the type of all the finite subgroups of \( H \) consisting of a list plus stability axioms.

Now consider any term \( Z : \text{fingrp} \to \text{fingrp} \) (examples of such terms abound: e.g. the center, the normalizer, the derived subgroup...). The abstraction theorem states that for any \( R : \alpha \to \alpha \to \text{Prop} \) compatible with the laws of \( H \) and for any \( G G' : \text{fingrp} \to \text{fingrp} \) (examples of \( Z \) and \( R \) are the relation on subgroups induced by \( R \). Given this, we can prove the following properties:

- for any \( G, ZG \subseteq G \) (if we take \( R : x y \to x \in G \));
- for any \( G, \) any \( \phi \) a morphism of \( H, \phi(ZG) = Z \phi(G) \) (if we take \( R : x y \to y = \phi(x) \)). It entails that \( ZG \) is a characteristic subgroup of \( H \).

For a complete \texttt{Coq} formalization of this, please refer to the online source code [9].

**V. CONCLUSION**

The system presented here allows to distinguish clearly via typing which expressions will be computationally meaningful after extraction. It allows us to define a notion of parametricity for which relations lie in the sort of propositions. We set here the theoretical foundation for an implementation of a \texttt{Coq} tactic that constructs proof terms by parametricity. A first prototype of such a tactic can be found online [9].
