Localization of global norms and robust a posteriori error control for transmission problems with sign-changing coefficients

Patrick Ciarlet Jr.† Martin Vohralík‡
March 30, 2018

Abstract

We present a posteriori error analysis of diffusion problems where the diffusion tensor is not necessarily symmetric and positive definite and can in particular change its sign. We first identify the correct intrinsic error norm for such problems, covering both conforming and nonconforming approximations. It combines a dual (residual) norm together with the distance to the correct functional space. Importantly, we show the equivalence of both these quantities defined globally over the entire computational domain with the Hilbertian sums of their localizations over patches of elements. In this framework, we then design a posteriori estimators which deliver simultaneously guaranteed error upper bound, global and local error lower bounds, and robustness with respect to the (sign-changing) diffusion tensor. Robustness with respect to the approximation polynomial degree is achieved as well. The estimators are given in a unified setting covering at once conforming, nonconforming, mixed, and discontinuous Galerkin finite element discretizations in two or three space dimensions. Numerical results illustrate the theoretical developments.

Key words: noncoercive problem, sign change, metamaterial, a posteriori error estimate, dual norm, distance to energy space, localization, equivalence local–global, minimization, best approximation, equilibrated flux, unified framework, robustness, finite element methods

1 Introduction

Let \( \Omega \subset \mathbb{R}^d \), \( 1 \leq d \leq 3 \), be an open polytope (polygon for \( d = 2 \), polyhedron for \( d = 3 \)) with a Lipschitz-continuous boundary \( \partial \Omega \), \( \Sigma \) a tensor-valued diffusion tensor, and \( f \) a datum. We consider the following problem: find \( u : \Omega \to \mathbb{R} \) such that

\[
-\nabla \cdot (\Sigma \nabla u) = f \quad \text{in } \Omega ,
\]
\[
u = 0 \quad \text{on } \partial \Omega .
\]

(1.1a) (1.1b)

In contrast to the usual setting, cf. Ciarlet [23], we relax the assumption of \( \Sigma \) being positive definite (and symmetric). Such a situation arises as a model problem in electromagnetism for interfaces between dielectrics and (negative) metamaterials or metals, see, e.g., Bonnet-BenDhia et al. [11] or Wallen et al. [53] and the references therein. The exemplar situation is the case where \( \Omega \) is composed of two subdomains \( \Omega_+ \) and \( \Omega_- \) of nonzero measure such that \( \Sigma|_{\Omega_+} = \sigma_+ I \) and \( \Sigma|_{\Omega_-} = \sigma_- I \), where \( \sigma_+ > 0 \) and \( \sigma_- < 0 \) are two scalars and \( I \) is the identity tensor.

We will call \( u \in H^1_0(\Omega) \) a weak solution of (1.1) if

\[
(\Sigma \nabla u, \nabla v) = (f, v) \quad \forall v \in H^1_0(\Omega).
\]

Conditions for well-posedness (existence, uniqueness, and continuous dependence on the data) of the general problem (1.2) follow from the celebrated Banach–Nečas–Babuška (also called Brezzi–Babuška or inf–sup) theorem, cf., e.g., Ern and Guermond [30, Theorem 2.6]. They have recently been revisited via the T-coercivity approach, see, e.g., Bonnet-BenDhia et al. [10] or Chesnel and Ciarlet [20] and the references therein. Precisely, the definition of an appropriate operator \( T \) is equivalent to the explicit realization of the inf–sup condition for the exact problem (1.2). Moreover, the same technique can be applied at the discrete level. Conception of numerical approximations, their well-posedness, and a priori error estimates have been addressed in [20, 9] in the conforming finite element context and in [21] in the nonconforming finite element and discontinuous Galerkin context.

A posteriori error analysis for problems of type (1.1) has likewise been started recently. In particular, Nicaise and Venel [39] bound the error between the known finite element approximation \( u_h \) and the unknown weak solution \( u \) given by (1.2) by a computable a posteriori indicator. The bound, however, features an unknown generic constant. The dependence of the quality of the estimator on the tensor \( \Sigma \) (on the ratio, or contrast, \( \sigma_+ / \sigma_- \) in the simplest setting) is, unfortunately, not traced; numerical experiments indicate deterioration of the behavior (so-called non-robustness) when the contrast is approaching the set of forbidden values given by an interval to which the value \(-1\) always belongs. In [39], there is also a need for a discrete version of the trace lifting operator, both in the analysis and in the implementation. The previous contributions on diffusion problems with jumping coefficients, see Bernardi and Verfürth [6], Ainsworth [1], or [52] and the references therein, only study the standard positive definite case.

In terms of a posteriori analysis, there are four goals of this contribution: firstly, we want to derive a posteriori error estimates which are guaranteed, certifying the maximal error and featuring no unknown constant. Secondly, we wish them to be robust with respect to the jumps and sign changes in the tensor \( \Sigma \). The adaptive mesh refinement based on the a posteriori error estimators developed in this work produces in particular in our numerical experiments sequences of meshes leading to optimal decay rates for an arbitrarily singular solution. Thirdly, we want to develop a unified framework covering all standard numerical methods. We achieve this via the concept of flux and potential reconstructions, following Prager and Synge [42], Ladèvèze and Leguillon [36], Kelly [34], Destuynder and Métivet [26], Ladevèze and Leguillon [36], and Braess and Schöberl [13] for equilibrated fluxes, Prager and Synge [42], Destuynder and Métivet [25], Ainsworth [1], or Carstensen and Merdon [18] for the potentials, and the unifying frameworks in Nicaise et al. [40], Repin [43], Ainsworth [2], Carstensen et al. [16], Becker et al. [5], or [52, 31, 32], see also the references therein. Fourthly and lastly, in extension of Braess et al. [12] for conforming finite elements and of [32, 33] for nonconforming, mixed, and discontinuous Galerkin finite elements, we obtain robustness with respect to the approximation polynomial degree.

The key point for obtaining the above-discussed properties is a proper choice of the way the error is measured. For conforming (lying in the space \( H^1_0(\Omega) \)) approximations, Verfürth [49], Chaillou and Suri [19], Veeser and Verfürth [46], Kreuzer and Süli [35], and [52, 29, 31] used the intrinsic problem-dependent norm given by the dual norm of the residual stemming from the weak formulation. We articulate here two goals. We first identify a proper generalization of this concept to our setting, including nonconforming approximations \( u_h \notin H^1_0(\Omega) \). The norm in which we measure the error is in particular given by

\[
|||v|||^2 := \max_{\varphi \in H^1_0(\Omega), \|\varphi\| = 1} (\Sigma \nabla \varphi, \nabla \varphi)^2 + \min_{\zeta \in H^1_0(\Omega)} \|\nabla \varphi - \zeta\|^2 + \sum_{e \in \mathcal{E}} h_e^{-1} |||\Pi_e^0 v|||^2.
\]  

(1.3)

Here \( v \) lies in \( H^1(\mathcal{T}_h) \), the broken Sobolev space, see (2.4) below, and \( \nabla \varphi \) is the discrete gradient defined below by (2.7). For \( v = u - u_h \), the first term above is the dual norm of the residual, the second one is the distance to the energy space in a gradient seminorm, and the last one evaluates the size of the mean values of jumps in the approximate solution \( u_h \). Secondly, we prove that \( |||\cdot|||^2 \) as well as both its components \( |||\cdot||| \), (first term in (1.3)) and \( |||\cdot|||^2 \), (last two terms in (1.3)) are equivalent to the Hilbertian sums of their localizations on patches of elements. These results seem to be of independent interest, stating a local–global equivalence for norms that are only global at a first sight. For dual (residual) norms, a result of this type has probably first been shown in Babuška and Miller [4, Theorem 2.1.1], and may be deduced from more recent a posteriori analyses, see in particular Carstensen and Funken [17], Morin et al. [38], Verfürth [48, 50], Veeser and Verfürth [46], Cohen et al. [24], and the references therein, typically for piecewise polynomial approximations. It has recently been extended in [8] to any bounded linear functional on the Sobolev space \( W^{1,p}_0(\Omega), p > 1 \). Galerkin orthogonality with respect to lowest-order modes turns out to be crucial here for
one direction of the equivalence. For the distance to the energy space, our localization result seems to be new, although a clue can be found in a posteriori error estimates for nonconforming finite element methods on piecewise polynomial spaces, see, e.g., [16, Theorem 5.1], the survey [32], and the references therein. We also cite Veeser [45] who recently proved that local and global best-approximation errors in the energy norm are equivalent for piecewise polynomial spaces. Here, we derive the localization results on the entire broken Sobolev space $H^1(T_h)$ and give direct and minimal proofs with clearly identified constants that only depend on mesh shape regularity and on the space dimension. This in particular gives robustness with respect to the tensor $\Sigma$ and does not request one to work with piecewise polynomial spaces. Computable upper bounds on the generic constants are also indicated. In a posteriori error analysis, these results allow to pass from merely global to actually local efficiency, namely in [49, 46, 52, 29, 31] and in the references therein.

Our paper is organized as follows. Section 2 sets the notation and assumptions and identifies and examines the intrinsic norm $\|\cdot\|$. Section 3 resumes our general findings about the localization of global norms. A posteriori estimates in an abstract framework for all standard numerical approximations of problem (1.1) then form the content of Section 4. Finally, Section 5 illustrates our theoretical developments on two numerical examples, whereas Section 6 gives some concluding remarks and outlook.

2 Setting

This section introduces the notation, assumptions, and discusses in detail the choice of the way we will measure the error in numerical approximations of problem (1.1).

2.1 Notation

Let $\{T_h\}_h$ be a family of simplicial partitions of the domain $\Omega$, i.e., $\cup_{K \in T_h} K = \overline{\Omega}$ for all $T_h$, any element $K \in T_h$ for any mesh $T_h$ is a closed simplex, and the intersection of two different simplices in one mesh $T_h$ is either empty, a vertex, or their common 1-dimensional face, $1 \leq l \leq d - 1$. The set of vertices will be denoted by $V_h$; it is composed of interior vertices $V_h^{int}$ and vertices located on the boundary $V_h^{ext}$. For element $K \in T_h$, $V_K$ denotes the set of its vertices. For a vertex $a \in V_h$, $T_a$ stands for the patch of the elements of $T_h$ which share $a$, for $\omega_a$ the corresponding open subdomain, and $\psi_a$ for the continuous, piecewise affine “hat” function which takes value 1 at the vertex $a$ and zero at the other vertices.

The mesh $(d - 1)$-dimensional faces are collected in the set $E_h$, with interior faces $E_h^{int}$ and boundary faces $E_h^{ext}$. A generic face is denoted by $e$ and its diameter by $h_e$. For any $e \in E_h$, $n_e$ stands for the unit normal vector to $e$; the orientation is arbitrary but fixed for $e \in E_h^{int}$ and points outwards of $\Omega$ for $e \in E_h^{ext}$. We will use the jump operator $[\cdot]$ yielding the difference evaluated along $n_e$ of the traces of the argument from the two mesh elements that share $e \in E_h^{int}$ and the actual trace for $e \in E_h^{ext}$. Similarly, $\{\cdot\}$ stands for the mean value of the traces from adjacent mesh elements on faces from $E_h^{int}$ and the actual trace on $E_h^{ext}$. We denote by $\Pi_h^0$ the $L^2(e)$-orthogonal projection onto constants (mean value) on a face $e \in E_h$.

For a $d$-dimensional subdomain $\omega$ of $\Omega$, we use $\langle \cdot, \cdot \rangle_\omega$ to denote the $L^2(\omega)$ or $|L^2(\omega)|^d$ scalar product and $\|\cdot\|_\omega$ for the associated norm; shall $\omega = \Omega$, the subscript is dropped. For $(d - 1)$-dimensional subdomains, we similarly use $\langle \cdot, \cdot \rangle_\omega$ and $\|\cdot\|_\omega$.

2.2 Assumptions

Throughout the paper, we shall suppose the following:

Assumption 2.1 (Setting). We suppose that

- the family $\{T_h\}_h$ is shape regular in the sense that there exists a constant $\kappa_T > 0$ such that, for all triangulations $T_h$, $\max_{K \in T_h} h_K / \varrho_K \leq \kappa_T$, where $h_K$ is the diameter of $K$ and $\varrho_K$ is the diameter of the largest ball inscribed in $K$;
- $\Sigma \in [L^\infty(\Omega)]^{d \times d}$;
- $f \in L^2(\Omega)$;
• there exists a linear bijective operator $T : H^1_0(\Omega) \to H^1_0(\Omega)$, cf. [20, Definition 3], bounded in the sense that $\|\nabla (Tv)\| \leq \|T\| \|\nabla v\|$ for all $v \in H^1_0(\Omega)$, $\|T\| < \infty$, and such that the bilinear form in (1.2) is $T$-coercive in the sense that $(\Sigma \nabla v, \nabla (Tv)) \geq \alpha \|\nabla v\|^2$ for all $v \in H^1_0(\Omega)$, $\alpha > 0$.

Then one immediately obtains:

**Corollary 2.2** (Weak solution). Under Assumption 2.1, there exists a well-posed solution of problem (1.1) in the sense (1.2). It satisfies $u \in H^1_0(\Omega)$ and $\sigma := -\Sigma \nabla u \in H(\text{div}, \Omega)$ with $\nabla \sigma = f$.

### 2.3 Intrinsic norm in the conforming setting

Let, for the moment, $v \in H^1_0(\Omega)$ and $\nabla_\theta = \nabla$. The weak formulation (1.2) and Assumption 2.1 suggest the intrinsic norm

$$\|v\|_* := \max_{\varphi \in H^1_0(\Omega) : \|\nabla \varphi\| = 1} (\Sigma \nabla_\theta v, \nabla \varphi);$$

(2.1a)

this writing takes immediately the form we need in this paper, for $v$ from the broken Sobolev space $H^1(\mathcal{T}_h)$ and the discrete gradient $\nabla_\theta$ defined below. We define the local versions of (2.1a), for each vertex $a \in \mathcal{V}_h$ and the corresponding patch subdomain $\omega_a$, as

$$\|v\|_{*, \omega_a} := \max_{\varphi \in H^1_0(\omega_a) : \|\nabla \varphi\|_{\omega_a} = 1} (\Sigma \nabla_\theta v, \nabla \varphi)_{\omega_a}.$$

(2.1b)

For $v \in H^1_0(\Omega)$, the Cauchy–Schwarz inequality implies

$$\frac{(\Sigma \nabla v, \nabla (Tv))}{\|\nabla (Tv)\|} \leq \|v\|_* \leq \|\Sigma \nabla v\| \quad \forall v \in H^1_0(\Omega),$$

(2.2)

and the boundedness and coercivity of the operator $T$ and the boundedness of the tensor $\Sigma$ allow to further confine

$$\frac{\alpha}{\|T\|} \|\nabla v\| \leq \|v\|_* \leq \|\Sigma\|_{\infty} \|\nabla v\| \quad \forall v \in H^1_0(\Omega),$$

(2.3)

so that $\|v\|_*$ is indeed a norm on the space $H^1_0(\Omega)$, equivalent to the canonical norm $\|\nabla v\|$. Note, however, that the equivalence constants $\frac{\alpha}{\|T\|}$ and $\|\Sigma\|_{\infty}$ are setting- and problem-dependent (not robust), see Remark 5.1 below for a discussion of a particular example. Remark also that $(\Sigma \nabla v, \nabla v)$ may become negative, which excludes the notion itself of an energy norm; on the other hand $\|v\|_* = \|\nabla v\|$ in the case where $\Sigma = I$, so that $\|v\|_*$ is a natural extension of the canonical norm of the Laplace operator.

### 2.4 Broken Sobolev space and broken and discrete gradients

In order to make our analysis as general as possible, taking in particular into account nonconforming and discontinuous Galerkin methods, we will henceforth often work with the broken Sobolev space $H^1(\mathcal{T}_h)$ related to the mesh $\mathcal{T}_h$,

$$H^1(\mathcal{T}_h) := \{ v \in L^2(\Omega); v|_K \in H^1(K) \quad \forall K \in \mathcal{T}_h \}.

(2.4)

The corresponding broken gradient $\nabla_h$ is given by, for $v \in H^1(\mathcal{T}_h)$,

$$\nabla_h v|_K = \nabla v|_K \quad \forall K \in \mathcal{T}_h;

(2.5)

one simply applies the usual weak gradient elementwise. All the analysis of the present paper holds for the broken gradient $\nabla_h$. Unfortunately, with $\nabla_h$, it is not possible to directly apply our results to certain numerical methods. Indeed, we will need to suppose Assumption 2.4 below, and this typically does not hold with $\nabla_h$ for certain discontinuous Galerkin methods. For this reason, following [32, 33], we are lead to present our results for a further generalization of the concept of the broken gradient.

For each face $e \in \mathcal{E}_h$, let $\mathcal{T}_e$ regroup the (one or two) mesh elements sharing the face $e$. We let $V^0(\mathcal{T}_e)$ stand for piecewise constant vectors on $\mathcal{T}_e$, i.e., $v_h|_K \in \mathbb{P}_0(K)^d$ for all $K \in \mathcal{T}_e$. Alternatively, vectors $v_h$ such that $v_h|_K \in [\mathbb{P}_0(K)]^d + \mathbb{P}_0(K)^d$ for all $K \in \mathcal{T}_e$ (piecewise lowest-order Raviart–Thomas–Nédélec space) could also be used. In both cases, $v_h \cdot n_e$ is constant for $v_h \in V^0(\mathcal{T}_e)$. Let $v \in H^1(\mathcal{T}_h)$. Following, e.g., Di
Pietro and Ern [27, Section 4.3] and the references therein, where these concepts are often employed, we define the lifting operator $L_e : L^2(e) \to V^0(T_e)$ by

$$ (L_e([v]), v_h)_{T_e} = \langle [v_h] \cdot n_e, [v] \rangle_e \quad \forall v_h \in V^0(T_e). \quad (2.6) $$

We then extend $L_e([v])$ by zero outside of $T_e$. For a parameter $\theta \in \{-1, 0, 1\}$, the discrete gradient $\nabla_\theta v \in [L^2(\Omega)]^d$ is given by

$$ \nabla_\theta v := \nabla_h v - \theta \sum_{e \in \mathcal{E}_h} L_e([v]). \quad (2.7) $$

We observe that $\nabla_\theta v = \nabla_h v$ when $\theta = 0$ or when the jumps of $v$ are of mean value 0, i.e., $\langle [v] \rangle_e = 0$ for all $e \in \mathcal{E}_h$. Similarly, both broken and discrete gradients are consistent extensions of the weak gradient $\nabla$ in the sense that

$$ \nabla_\theta v = \nabla_h v = \nabla v \quad \forall v \in H^1_0(\Omega). \quad (2.8) $$

### 2.5 Nonconformity evaluation

An important observation is that $\|\cdot\|_s$ given by (2.1a) is merely a seminorm on the broken Sobolev space $H^1(T_h)$. Consequently, it is not sufficient to evaluate the error therein, and we are lead to quantify the nonconformity $H^1(T_h) \not\subset H^1(\Omega)$. An intrinsic measure here is simply the distance to the energy space $H^1(\Omega)$, $\min_{\zeta \in H^1(\Omega)} \|\nabla_\theta (v - \zeta)\|$ for $v \in H^1(T_h)$. As in this expression, only the gradient seminorm appears, we are finally lead to evaluate the nonconformity as

$$ \|v\|^2_\# := \min_{\zeta \in H^1(\Omega)} \|\nabla_\theta (v - \zeta)\|^2 + \sum_{e \in \mathcal{E}_h} h^{-1}_e \|\Pi^e_0[v]\|^2 \quad v \in H^1(T_h). \quad (2.9a) $$

The second term with the mean values of the jumps on the faces given by $\Pi^e_0[v]$ ensures the validity of the broken Poincaré–Friedrichs inequality and plays a key role in Lemma 2.3 below. Note also that scaling both or one term in (2.9a) by generic constants is possible. As local versions of (2.9a), we define

$$ \|v\|^2_{\#, \omega_a} := \min_{\zeta \in H^1(\omega_a)} \|\nabla_\theta (v - \zeta)\|^2 + \sum_{e \in \mathcal{E}_h, a \in e} h^{-1}_e \|\Pi^e_0[v]\|^2 \quad (2.9b) $$

for each vertex $a \in \mathcal{V}_h$ and the corresponding patch subdomain $\omega_a$. Here

$$ H^1_{\#}(\omega_a) := H^1(\omega_a), \quad a \in \mathcal{V}_h^{\text{int}}, $$

$$ H^1_{\#}(\omega_a) := \{v \in H^1(\omega_a); v = 0 \text{ on } \partial \omega_a \cap \partial \Omega\}, \quad a \in \mathcal{V}_h^{\text{ext}}. \quad (2.10) $$

### 2.6 Intrinsic norm

Combining (2.1a) and (2.9a), we define the total intrinsic norm as

$$ \|v\|^2 = \|v\|^2_\# + \|v\|^2_T \quad v \in H^1(T_h). \quad (2.11) $$

We have the following simple but crucial result:

**Lemma 2.3** (Intrinsic norm). *Let the broken Sobolev space $H^1(T_h)$ be given by (2.4) and the discrete gradient $\nabla_\theta$ by (2.7) with $\theta \in \{-1, 0, 1\}$. Then $\|\cdot\|$ given by (2.11) defines a norm on $H^1(T_h)$.***

**Proof.** Clearly, $\|\alpha v\| = |\alpha| \|v\|$ and $\|v + w\| \leq \|v\| + \|w\|$ for any $\alpha \in \mathbb{R}$ and any $v, w \in H^1(T_h)$. Let now $\|v\| = 0$. Then the second term in (2.9a) implies that the jumps of $v$ are of mean value 0, $\langle [v] \rangle_e = 0$ for all $e \in \mathcal{E}_h$, and thus $\nabla_\theta = \nabla_h$. Consequently, for $s := \arg\min_{\zeta \in H^1(\Omega)} \|\nabla_h (v - \zeta)\|$, the broken Poincaré–Friedrichs inequality

$$ \|v - s\| \leq C_{\text{BF}, \Omega} h_\Omega \|\nabla_h (v - s)\|, $$

see Brenner [14] or [51], implies from the fact that the first term in (2.9a) vanishes that $v = s$ and thus $v \in H^1_0(\Omega)$. Finally, the equivalence (2.3) valid on the energy space $H^1_0(\Omega)$ shows that indeed $v = 0$. \qed
2.7 Evaluating the error by the dual norm of the residual and the distance to the energy space

When \( \Sigma = I \), there holds, for arbitrary \( u \in H^1_0(\Omega) \) and \( u_h \in H^1(T_h) \),

\[
\|\nabla \varphi(u - u_h)\|^2 = \max_{\varphi \in H^1_0(\Omega); \|\nabla \varphi\|=1} (\nabla \varphi(u - u_h), \nabla \varphi)^2 + \min_{\zeta \in H^1_0(\Omega)} \|\nabla \varphi(u - \zeta)\|^2, \tag{2.12}
\]

see Theorems 3.3 in [32, 28] and the references therein. Note that the present definition (2.9a) implies

\[
\|u - u_h\|_{\#}^2 = \min_{\zeta \in H^1_0(\Omega)} \|\nabla \varphi((u - u_h) - \zeta)\|^2 + \sum_{e \in E_h} h_e^{-1}\|\Pi_e^0[u - u_h]\|_e^2
\]

\[= \min_{\zeta \in H^1_0(\Omega)} \|\nabla \varphi(u_h - \zeta)\|^2 + \sum_{e \in E_h} h_e^{-1}\|\Pi_e^0[u_h]\|_e^2, \tag{2.13}
\]

since \( u \in H^1_0(\Omega) \) and since its jumps are zero. Thus \( \|u - u_h\|_{\#} \) is a distance of \( u_h \) to the space \( H^1_0(\Omega) \) and it simplifies to the energy distance \( \min_{\zeta \in H^1_0(\Omega)} \|\nabla \varphi(u_h - \zeta)\| = \min_{\zeta \in H^1_0(\Omega)} \|\nabla \varphi(u_h - \zeta)\| \) whenever the jumps of \( u_h \) are of mean value zero, \( \{\|u_h\|_e\}_e = 0 \) for all \( e \in E_h \). For \( \Sigma = I \), our intrinsic problem-dependent error thus takes the form

\[
\|u - u_h\|^2 = \|u - u_h\|^2 + \|u - u_h\|_{\#}^2 = \|\nabla \varphi(u - u_h)\|^2 + \sum_{e \in E_h} h_e^{-1}\|\Pi_e^0[u_h]\|_e^2,
\]

so that in particular \( \|u - u_h\| = \|\nabla \varphi(u - u_h)\| \) whenever the jumps of \( u_h \) are of mean value zero. In what concerns the first term \( \|u - u_h\|_1 \), using the dual norm definition (2.1a), equivalence (2.8) on \( H^1_0(\Omega) \), and the weak solution characterization (1.2), it takes the form

\[
\|u - u_h\|_1 = \max_{\varphi \in H^1_0(\Omega); \|\nabla \varphi\|=1} \left\{ (f, \varphi) - (\Sigma \nabla \varphi u_h, \nabla \varphi) \right\},
\]

so that this is nothing but the dual norm of the residual. Note that only this term remains whenever \( u_h \in H^1_0(\Omega) \); in this case \( \|u - u_h\| = \|u - u_h\|_1 \).

2.8 Orthogonality with respect to the hat functions

We conclude this introductory section by an assumption that will be crucial for some of the forthcoming results:

**Assumption 2.4** (Galerkin orthogonality with respect to \( \psi_a \)). There holds

\[
(\Sigma \nabla \varphi u_h, \nabla \psi_a)_{\omega_a} = (f, \psi_a)_{\omega_a} \quad \forall a \in V^\text{int}_h.
\]

This assumption is naturally satisfied in most Galerkin numerical approximations of problem (1.1), namely in various conforming, nonconforming, and discontinuous Galerkin finite elements. Application to mixed finite elements can be achieved along the lines of [32, Section 4.4].

3 Equivalent localization of global dual and distance norms

This section shows that two types of global norms, dual norms on the space \( H^1_0(\Omega) \) of the form \( \|\cdot\|_\# \) of (2.1a) and distance norms of the form \( \|\cdot\|_{\#} \) of (2.9a), admit an equivalence with their local versions of the respective forms \( \|\cdot\|_{\#_e} \) of (2.1b) and \( \|\cdot\|_{\#_\omega} \) of (2.9b). Let us note immediately that Assumption 2.4 is central for one direction in the first case. This may be seen as an extension of some previous results in [4, 17, 38, 48, 46, 24, 50, 31, 32] to the broken Sobolev space \( H^1(T_h) \) of (2.4). The presentation below is not necessarily linked to a posteriori error analysis and we find it of independent interest. We give direct and minimal proofs, with clearly identified constants that only depend on the mesh shape regularity \( \kappa_T \) and space dimension \( d \). All results here actually hold for any space dimension \( d \geq 1 \).
3.1 Some useful local inequalities

Some more definitions and tools will now be needed. Let first the patchwise Sobolev spaces be given by
\[
\begin{align*}
H^1_0(\omega_a) & := \{ v \in H^1(\omega_a); (v, 1)_{\omega_a} = 0 \}, \quad a \in \mathcal{V}_h^{\text{int}}, \\
H^1_0(\omega_a) & := \{ v \in H^1(\omega_a); v = 0 \text{ on } \partial\omega_a \cap \partial\Omega \}, \quad a \in \mathcal{V}_h^{\text{ext}}.
\end{align*}
\] (3.1)

It follows from [17, Theorem 3.1], [12, Section 3], see also [32, Lemma 3.12], that
\[
\| \nabla (\psi_av) \|_{\omega_a} \leq C_{\text{cont,PF}} \| \nabla v \|_{\omega_a} \quad \forall v \in H^1_0(\omega_a), \forall a \in \mathcal{V}_h,
\] (3.2)
where
\[
C_{\text{cont,PF}} := \max_{a \in \mathcal{V}_h} \{ 1 + C_{\text{PF,}\omega_a} h_{\omega_a} \| \nabla \psi_a \|_{\infty, \omega_a} \}
\] (3.3)
only depends on the shape regularity parameter \( \kappa_T \) and possibly on the space dimension \( d \). Here \( C_{\text{PF,}\omega_a} \) is the Poincaré–Friedrichs constant from
\[
\| v \|_{\omega_a} \leq C_{\text{PF,}\omega_a} h_{\omega_a} \| \nabla v \|_{\omega_a} \quad \forall v \in H^1_0(\omega_a),
\] (3.4)
see Payne and Weinberger [41] or Veeser and Verfürth [47].

Similarly, it follows as in [32, Lemma 3.13] and [33, Section 4] that
\[
\| \nabla_b (\psi_av) \|_{\omega_a} \leq C_{\text{cont,bPF}} \left( \| \nabla_b v \|_{\omega_a} + \sum_{e \in E_a, a \in e} h_{e}^{-1} \| \Pi^0_e[v] \|_2^2 \right)^{1/2},
\] (3.5)
\[
\forall v \in H^1(\mathcal{T}_h) \text{ with } (v, 1)_{\omega_a} = 0 \text{ when } a \in \mathcal{V}_h^{\text{int}},
\]
where \( C_{\text{cont,bPF}} := \max_{a \in \mathcal{V}_h} \{ 1 + C_{\text{bPF,}\omega_a} h_{\omega_a} \| \nabla \psi_a \|_{\infty, \omega_a} \} \) only depends on the shape regularity parameter \( \kappa_T \) and possibly on the space dimension \( d \). Here \( C_{\text{bPF,}\omega_a} \) is the constant from the broken Poincaré–Friedrichs inequality
\[
\| v \|_{\omega_a} \leq C_{\text{bPF,}\omega_a} h_{\omega_a} \left( \| \nabla_b v \|_{\omega_a}^2 + \sum_{e \in E_a, a \in e} h_{e}^{-1} \| \Pi^0_e[v] \|_2^2 \right)^{1/2},
\] (3.6)
\[
\forall v \in H^1(\mathcal{T}_h) \text{ with } (v, 1)_{\omega_a} = 0 \text{ when } a \in \mathcal{V}_h^{\text{int}},
\]
see Brenner [14] or [51].

Finally, as the spaces \( \mathbf{V}^0(\mathcal{T}_e) \) in the definition (2.7) of the discrete gradient consist of low-order polynomials, the inverse inequality gives
\[
\| \mathbf{v}_h, \mathbf{e}_h \|_e \leq C_{\text{inv}} h_{e}^{-1/2} \| \mathbf{v}_h \|_K \quad \forall K \in \mathcal{T}_h, \forall e \in \mathcal{E}_K, \forall \mathbf{v}_h \in \mathbf{V}^0(\mathcal{T}_e),
\] (3.7)
where \( C_{\text{inv}} \) only depends on \( \kappa_T \) and \( d \).

3.2 Localization of dual (residual) norms

The following is our localization result for the dual norm of the residual \( \| u - u_h \|_* \) defined by (2.1a), with the patchwise contributions \( \| u - u_h \|_{\ast, \omega_a} \) given by (2.1b):

**Proposition 3.1** (Localization of the dual norm of the residual). Let \( u \) be the weak solution given by (1.2) and let \( u_h \in H^1(\mathcal{T}_h) \) satisfying Assumption 2.4 be arbitrary. Then
\[
\| u - u_h \|_* \leq (d + 1)^{1/2} C_{\text{cont,PF}} \left( \sum_{a \in \mathcal{V}_h} \| u - u_h \|_{\ast, \omega_a}^2 \right)^{1/2},
\] (3.8a)
\[
\left\{ \frac{1}{d + 1} \sum_{a \in \mathcal{V}_h} \| u - u_h \|_{\ast, \omega_a}^2 \right\}^{1/2} \leq \| u - u_h \|_*,
\] (3.8b)
Theorem 3.3
Recall that $C$ immediately follows.

Similarly, $\phi$ where $\Pi$ under the hat functions orthogonality condition for the space $H$ always holds

$$\|u - u_h\|_\star = (d + 1)^{1/2} \left\{ \sum_{a \in V_h} C^2 \|u - u_h\|_{\omega_a} \right\}^{1/2}$$

(3.9)

immediately follows.

This proposition is an immediate consequence of the following general theorem of independent interest. Recall that $C_{\text{cont,PF}}$ is the constant from inequality (3.2):

Theorem 3.3 (Localization of a dual norm with $\psi_a$-Galerkin orthogonality). Let $v \in [L^2(\Omega)]^d$. Then, under the hat functions orthogonality condition

$$\langle v, \nabla \psi_a \rangle_{\omega_a} = 0 \quad \forall a \in V^\text{int}_h,$$

there holds

$$\max_{\varphi \in H^1_0(\Omega); \|\nabla \varphi\| = 1} \langle v, \nabla \varphi \rangle^2 \leq (d + 1)C^2_{\text{cont,PF}} \sum_{a \in V_h} \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\| = 1} \langle v, \nabla \varphi \rangle^2_{\omega_a}.$$  

(3.11a)

There always holds

$$\sum_{a \in V_h} \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\| = 1} \langle v, \nabla \varphi \rangle^2_{\omega_a} \leq (d + 1) \max_{\varphi \in H^1_0(\Omega); \|\nabla \varphi\| = 1} \langle v, \nabla \varphi \rangle^2.$$  

(3.11b)

Proof. Let $\varphi \in H^1_0(\Omega)$ with $\|\nabla \varphi\| = 1$ be fixed. The partition of unity by the hat functions $\psi_a$, $\sum_{a \in V_h} \psi_a = 1$, and the Galerkin orthogonality with respect to $\psi_a$ expressed by (3.10) give

$$\langle v, \nabla \varphi \rangle = \sum_{a \in V_h} \langle v, \nabla (\psi_a \varphi) \rangle = \sum_{a \in V_h} \langle v, \nabla (\psi_a \varphi) \rangle_{\omega_a} + \sum_{a \in V^\text{ext}_h} \langle v, \nabla (\psi_a \varphi) \rangle_{\omega_a},$$

where $\Pi_{0,\omega_a}$ is the mean value of the function $\varphi$ on the patch $\omega_a$. There holds $(\varphi - \Pi_{0,\omega_a})_{\omega_a} \in H^1_0(\omega_a)$ for the space $H^1_0(\omega_a)$ given by (3.1) and $(\psi_a(\varphi - \Pi_{0,\omega_a}))_{\omega_a} \in H^1_0(\omega_a)$ for an interior vertex $a \in V^\text{int}_h$. Similarly, $\varphi|_{\omega_a} \in H^1(\omega_a)$ and $(\psi_a \varphi)|_{\omega_a} \in H^1(\omega_a)$ for a boundary vertex $a \in V^\text{ext}_h$. Thus, passing to a maximum and using inequality (3.2) yields, for any interior vertex $a \in V^\text{int}_h$,

$$\langle v, \nabla (\psi_a (\varphi - \Pi_{0,\omega_a}) \varphi) \rangle_{\omega_a} = \|\nabla (\psi_a (\varphi - \Pi_{0,\omega_a}) \varphi) \|_{\omega_a} \langle v, \nabla (\psi_a (\varphi - \Pi_{0,\omega_a}) \varphi) \rangle_{\omega_a} \leq \|\nabla (\psi_a (\varphi - \Pi_{0,\omega_a}) \varphi) \|_{\omega_a} \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\| = 1} \langle v, \nabla \varphi \rangle_{\omega_a} \leq C_{\text{cont,PF}} \|\nabla \varphi \|_{\omega_a} \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\| = 1} \langle v, \nabla \varphi \rangle_{\omega_a},$$

finally employing that the gradient of a constant vanishes. A similar estimate holds for $a \in V^\text{ext}_h$. Thus, the Cauchy–Schwarz inequality gives

$$\langle v, \nabla \varphi \rangle^2 \leq C^2_{\text{cont,PF}} \sum_{a \in V_h} \|\nabla \varphi\|^2_{\omega_a} \sum_{a \in V_h} \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\| = 1} \langle v, \nabla \varphi \rangle^2_{\omega_a}.$$  

Now the fact that each simplex has $d + 1$ vertices gives

$$\sum_{a \in V_h} \|\nabla \varphi\|^2_{\omega_a} = \sum_{a \in V_h} \sum_{K \in T_a} \|\nabla \varphi\|^2_{K} = \sum_{K \in T_h} \sum_{a \in V_K} \|\nabla \varphi\|^2_{K} = (d + 1)\|\nabla \varphi\|^2,$$

(3.12)
so that the premise $\|\nabla \varphi\| = 1$ finally yields (3.11a).

The converse estimate (3.11b) does not need the hypothesis (3.10). Let $a \in \mathcal{V}_h$ and let $\zeta^a \in H^1_0(\omega_a)$ be defined by the lifting

$$(\nabla \zeta^a, \nabla \varphi)_{\omega_a} = (\varphi, \nabla \varphi)_{\omega_a} \quad \forall \varphi \in H^1_0(\omega_a).$$

Then

$$(\varphi, \nabla \zeta^a)_{\omega_a} = (\nabla \zeta^a, \nabla \zeta^a)_{\omega_a} = \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\|_{\omega_a} = 1} (\nabla \zeta^a, \nabla \varphi)_{\omega_a}^2 = \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\|_{\omega_a} = 1} (\varphi, \nabla \varphi)_{\omega_a}^2.$$ 

Consequently, taking $\zeta := \sum_{a \in \mathcal{V}_h} \zeta^a \in H^1_0(\Omega)$,

$$\sum_{a \in \mathcal{V}_h} \max_{\varphi \in H^1_0(\omega_a); \|\nabla \varphi\|_{\omega_a} = 1} (\varphi, \nabla \varphi)_{\omega_a}^2 = \sum_{a \in \mathcal{V}_h} (\varphi, \nabla \zeta^a)_{\omega_a} = (\varphi, \nabla \zeta) \leq \max_{\varphi \in H^1_0(\Omega); \|\nabla \varphi\| = 1} (\varphi, \nabla \varphi)\|\nabla \varphi\|,$$

where we finally passed to the maximum. Noticing that

$$\|\nabla \zeta\|^2 = \sum_{K \in \mathcal{T}_h} \sum_{a \in \mathcal{V}_K} (\nabla \zeta^a)|_K \|_{K}^2 \leq (d + 1) \sum_{a \in \mathcal{V}_h} \|\nabla \zeta^a\|_{\omega_a}^2,$$

we arrive at (3.11b).

\[\Box\]

**Remark 3.4** (Further generalization). *Theorem 3.3 has recently been extended to any bounded linear functional on the Sobolev space $W^{1,p}_0(\Omega), p > 1$, in [8].*

### 3.3 Localization of distances to the energy space

Recall that $d$ is the space dimension, $\nabla_b$ is the broken gradient given by (2.5), $\nabla_b$ is the discrete gradient given by (2.7) with the parameter $\theta \in \{-1, 0, 1\}$, and that the constants $C_{\text{cont,bPF}}$ and $C_{\text{inv}}$ are respectively given by (3.5) and (3.7). It appears that the distance $\|u - u_h\|_\#$ defined in (2.9a) admits a similar localization property for the contributions $\|u - u_h\|_{\#, \omega_a}$ defined in (2.9b), as this was the case for $\|u - u_h\|_*$ in Proposition 3.1:

**Proposition 3.5** (Localization of the distance to the energy space). *Let $u \in H^1_0(\Omega)$ and $u_h \in H^1(\mathcal{T}_h)$ be arbitrary. Then

$$\|u - u_h\|_{\#}^2 \leq C^2_{\text{loc}} \sum_{a \in \mathcal{V}_h} \|u - u_h\|_{\#, \omega_a}^2,$$

$$\sum_{a \in \mathcal{V}_h} \|u - u_h\|_{\#, \omega_a}^2 \leq (d + 1) \|u - u_h\|_{\#}^2,$$

where

$$C^2_{\text{loc}} := 8(d + 1)C^2_{\text{cont,bPF}} + \frac{1}{d} (2\theta)^2 (d + 1)C^2_{\text{inv}} + 1 + \frac{1}{d} (8\theta)^2 (d + 1)^3 C^2_{\text{cont,bPF}} C^2_{\text{inv}}. \tag{3.13}$$

To prove this result, the following theorem of independent interest will be crucial:

**Theorem 3.6** (Localization of a global distance for jumps of mean value zero). *Let $v \in H^1(\mathcal{T}_h)$. Then, when the jumps of $v$ have zero mean values, i.e.

$$\langle [v], 1 \rangle = 0 \quad \forall e \in \mathcal{E}_h,$$

there holds

$$\min_{\zeta \in H^1_0(\Omega)} \|\nabla_b(v - \zeta)\|_{\omega_a}^2 \leq (d + 1)C^2_{\text{cont,bPF}} \sum_{a \in \mathcal{V}_h} \min_{\zeta \in H^1_0(\omega_a)} \|\nabla_b(v - \zeta)\|_{\omega_a}^2. \tag{3.15a}$$

There always holds

$$\sum_{a \in \mathcal{V}_h} \min_{\zeta \in H^1_0(\omega_a)} \|\nabla_b(v - \zeta)\|_{\omega_a}^2 \leq (d + 1) \min_{\zeta \in H^1_0(\Omega)} \|\nabla_b(v - \zeta)\|_{\omega_a}^2; \tag{3.15b}$$

(3.15b) also holds for the discrete gradient $\nabla_b$ in place of the broken gradient $\nabla_b$.  

---

9
Proof. The second claim (3.15b) is immediate, as local-best approximation is always subordinate to the global-best one:

$$\sum_{\zeta \in V_h} \min_{v \in H^1_0(\omega)} \| \nabla_b(v - \zeta) \|_{H^1_0(\omega)}^2 \leq \min_{\zeta \in H^1_0(\Omega)} \sum_{\zeta \in V_h} \| \nabla_b(v - \zeta) \|_{H^1_0(\Omega)}^2 = (d + 1) \min_{\zeta \in H^1_0(\Omega)} \| \nabla_b(v - \zeta) \|_{H^1_0(\Omega)}^2.$$

In the inequality, we have used that restriction of any $\zeta \in H^1_0(\Omega)$ to the patch subdomain $\omega$ for any vertex $a \in V_h$ lies in the space $H^1_0(\omega)$ given by (2.10); in the equality, the fact that each element $K \in T_h$ lies in $(d + 1)$ patches has been employed as in (3.12). This estimate is obviously the same for $\nabla_b v$ replaced by $\nabla_a v$. The rest of the proof is thus dedicated to showing the first claim (3.15a).

Let, for a given vertex $a \in V_h$, $s^a$ be defined by the orthogonal projection of the function $\psi a v$ onto the space $H^1_0(\omega)$,

$$s^a := \arg \min_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi a v - \zeta) \|_{H^1_0(\omega)}; \tag{3.16}$$

equivalently, $s^a \in H^1_0(\omega)$ solves

$$(\nabla s^a, \nabla \zeta)_{H^1_0(\omega)} = (\nabla_b(\psi a v), \nabla \zeta)_{H^1_0(\omega)}, \quad \forall \zeta \in H^1_0(\omega).$$

Extending $s^a$ by zero outside of $\omega$ and setting $s := \sum_{a \in V_h} s^a \in H^1_0(\Omega)$, we have, also employing the partition of unity $\sum_{a \in V_h} \psi a | K = 1 | K$,

$$\min_{\zeta \in H^1_0(\Omega)} \| \nabla_b(v - \zeta) \|_{H^1_0(\Omega)}^2 \leq \| \nabla_b(v - s) \|_{H^1_0(\Omega)}^2 = \sum_{K \in T_h} \| \nabla_b(v - s) \|_{H^1_0(K)}^2$$

$$= \sum_{K \in T_h} \left( \sum_{a \in V_K} \| \nabla_b(\psi a v - s^a) \|_{H^1_0(K)} \right)^2 \leq (d + 1) \sum_{a \in V_h} \| \nabla_b(\psi a v - s^a) \|_{H^1_0(\omega)}^2. \tag{3.17}$$

The fact that $\psi a \zeta \in H^1_0(\omega)$ for any $\zeta \in H^1_0(\omega)$ gives from (3.16)

$$\| \nabla_b(\psi a v - s^a) \|_{H^1_0(\omega)} \leq \inf_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi a v - \zeta) \|_{H^1_0(\omega)}. \tag{3.18}$$

Let $H^1_{#,ext}(\omega) := H^1_0(\omega)$ for $a \in V^h_{#}$ and $H^1_{#,int}(\omega) := \{ \zeta \in H^1_0(\omega); (\zeta, 1)_{\omega} = (v, 1)_{\omega} \}$ for $a \in V^h_{int}$. Introducing this space allows us to restrain the arguments to mean value zero on vertices $a \in V^h_{int}$, so that we can employ inequality (3.5). Therein the jumps actually disappear thanks to the present simplifying assumption (3.14). In combination with the Cauchy–Schwarz inequality, we obtain

$$\inf_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi a v - \zeta) \|_{H^1_0(\omega)} \leq \inf_{\zeta \in H^1_{#,ext}(\omega)} \| \nabla_b(\psi a v - \zeta) \|_{H^1_0(\omega)} \leq C_{cont,bPF} \min_{\zeta \in H^1_{#,ext}(\omega)} \| \nabla_b(v - \zeta) \|_{H^1_0(\omega)}$$

$$= C_{cont,bPF} \min_{\zeta \in H^1_0(\omega)} \| \nabla_b(v - \zeta) \|_{H^1_0(\omega)}; \tag{3.19}$$

in the final equality, we have employed that the gradient of a constant on the patch $\omega$ vanishes. Collecting these results finishes the proof.

Proof of Proposition 3.5. The equality

$$\sum_{a \in V_h} \sum_{e \in K} h_e^{-1} \| \Pi^0_e[v] \|_e^2 = d \sum_{e \in K} h_e^{-1} \| \Pi^0_e[v] \|_e^2 \quad \forall v \in H^1(T_h) \tag{3.20}$$

follows immediately from the fact that each face is shared by $d$ vertices. The second claim of Proposition 3.5 then follows from inequality (3.15b) employed for the discrete gradient $\nabla_a$ and using definitions (2.9a) and (2.9b) together with property (2.13). We now turn to the proof of the first claim of Proposition 3.5.

Let $v \in H^1(T_h)$ be arbitrary (not subject to condition (3.14)) and recall that by definition (2.9a), one has $\| v \|_{#}^2 = \min_{\zeta \in H^1_0(\Omega)} \| \nabla_a(v - \zeta) \|_{H^1_0(\Omega)}^2 + \sum_{e \in \partial E} h_e^{-1} \| \Pi^0_e[v] \|_e^2$. From (3.20), the jump terms immediately take the local form requested in (2.9b). Denote $s_1 := \arg \min_{\zeta \in H^1_0(\Omega)} \| \nabla_a(v - \zeta) \|$ and $s_2 := \arg \min_{\zeta \in H^1_0(\Omega)} \| \nabla_b(v - \zeta) \|$. Then

$$\| v \|_{#}^2 \leq \| v \|_{#}^2 + \sum_{e \in \partial E} h_e^{-1} \| \Pi^0_e[v] \|_e^2 \leq (d + 1) \| v \|_{#}^2 + \sum_{e \in \partial E} h_e^{-1} \| \Pi^0_e[v] \|_e^2.$$
\(|\zeta\|\). The minimization property of \(s_1\) together with the discrete gradient definition (2.7) and the fact that the jumps of \(s_2\) are zero give

\[
\|\nabla_\theta(v - s_1)\|^2 \leq \|\nabla_\theta(v - s_2)\|^2 = \left\| \nabla_b(v - s_2) - \theta \sum_{e \in \mathcal{E}_h} L_e([v]) \right\|^2 \leq 2\|\nabla_b(v - s_2)\|^2 + 2|\theta|^2 \sum_{e \in \mathcal{E}_h} L_e([v])
\]

(3.21)

Recall that \(\mathcal{T}_e\) regroups the mesh elements sharing the face \(e\). Employing the definition (2.6) of the lifting \(L_e([v])\), the facts that \(L_e([v])\) is only supported on \(\mathcal{T}_e\) and that \(v_h \cdot n_e|_e\) is constant for \(v_h \in V^0(\mathcal{T}_e)\), the Cauchy–Schwarz inequality, and the inverse inequality (3.7), we easily infer, for each face \(e \in \mathcal{E}_h\),

\[
\|L_e([v])\|_{\mathcal{T}_e} = \sup_{v_h \in V^0(\mathcal{T}_e); \|v_h\|_{\mathcal{T}_e} = 1} \langle L_e([v]), v_h \rangle_{\mathcal{T}_e}
\]

\[
= \sup_{v_h \in V^0(\mathcal{T}_e); \|v_h\|_{\mathcal{T}_e} = 1} \langle \langle \nabla v_h \cdot n_e, [v] \rangle_e \rangle_e
\]

\[
= \sup_{v_h \in V^0(\mathcal{T}_e); \|v_h\|_{\mathcal{T}_e} = 1} \langle \langle \nabla v_h \cdot n_e, \Pi^0_e[v] \rangle_e \rangle_e
\]

\[
\leq C_{inv} h_e^{-1/2} \|\Pi^0_e[v]\|_e.
\]

Consequently, since every simplex has \(d + 1\) faces, we can estimate the last term in (3.21) as

\[
\left( \sum_{e \in \mathcal{E}_h} L_e([v]) \right)^2 \leq (d + 1) \sum_{e \in \mathcal{E}_h} \|L_e([v])\|^2_K \leq (d + 1) C_{inv}^2 \sum_{e \in \mathcal{E}_h} h_e^{-1} \|\Pi^0_e[v]\|_e^2.
\]

(3.22)

Finally, for the bound on \(\|\nabla_b(v - s_2)\|\), we use that \(s_2\) is the minimizer for the broken gradient \(\nabla_b\) and proceed as in the proof of Theorem 3.6. In particular, both (3.17) and (3.18) hold true, whereas in (3.19), we need to employ inequality (3.5) without assumption (3.14), yielding

\[
\inf_{\zeta \in H^2_b(\omega)} \|\nabla_b(v - \zeta)\|_{\omega} \leq C_{cont,bPF} \left( \min_{\zeta \in H^2_b(\omega)} \|\nabla_b(v - \zeta)\|_{\omega} + \sum_{e \in \mathcal{E}_h, a \in e} h_e^{-1} \|\Pi^0_e[v]\|_e^2 \right)^{1/2}.
\]

(3.23)

Consequently,

\[
\|\nabla_b(v - s_2)\|_\omega \leq 2(d + 1) C_{cont,bPF} \sum_{a \in V_h} \left( \min_{\zeta \in H^2_b(\omega)} \|\nabla_b(v - \zeta)\|_{\omega} + \sum_{e \in \mathcal{E}_h, a \in e} h_e^{-1} \|\Pi^0_e[v]\|_e^2 \right).
\]

This already gives an upper bound with a local minimization structure, and we are left to make reappear the discrete gradients in place of the broken ones. In order to do so, we proceed similarly to (3.21),

\[
\sum_{a \in V_h} \min_{\zeta \in H^2_b(\omega)} \|\nabla_b(v - \zeta)\|_{\omega} \leq 2 \sum_{a \in V_h} \min_{\zeta \in H^2_b(\omega)} \|\nabla_\theta(v - \zeta)\|_{\omega}^2 + 2|\theta|^2 \sum_{a \in V_h} \sum_{e \in \mathcal{E}_h} L_e([v]) \left\| \nabla_\theta(v - \zeta) \right\|_{\omega}^2 \leq 2 \sum_{a \in V_h} \min_{\zeta \in H^2_b(\omega)} \|\nabla_\theta(v - \zeta)\|_{\omega}^2 + 2|\theta|^2 (d + 1)^2 C_{inv}^2 \sum_{e \in \mathcal{E}_h} h_e^{-1} \|\Pi^0_e[v]\|_e^2,
\]

(3.24)

where we have used \(\sum_{a \in V_h} \sum_{e \in \mathcal{E}_h} L_e([v]) = (d + 1) \sum_{e \in \mathcal{E}_h} L_e([v])\) like in (3.12) and (3.22). Altogether,

\[
\|v\|_\#^2 \leq C_{loc}^2 \sum_{a \in V_h} \left( \min_{\zeta \in H^2_b(\omega)} \|\nabla_\theta(v - \zeta)\|_{\omega}^2 + \sum_{e \in \mathcal{E}_h, a \in e} h_e^{-1} \|\Pi^0_e[v]\|_e^2 \right),
\]

where \(C_{loc}^2\) is given by (3.13), and the proof is concluded using the property (2.13) to apply the derived result to \(v = u - u_h\).
4 Guaranteed, robust, and locally efficient a posteriori estimates in a unified framework

We present in this section our a posteriori estimates on the error in a numerical approximation of problem (1.1). The estimates give guaranteed global error upper bound (global reliability). Crucially, we achieve all robustness with respect to the jumps and anisotropy of the diffusion tensor \( \Sigma \), robustness with respect to the approximation polynomial degree, and local error lower bound (local efficiency); the latter in consequence of the localization results of Section 3. Our results are presented in an abstract framework, following [31, 32, 33]. This enables to cover at once basically any classical numerical method, in particular all types of conforming, nonconforming, mixed, and discontinuous Galerkin finite elements. The key idea is to build a piecewise polynomial \( H^1_0(\Omega) \)-conforming potential reconstruction and a piecewise polynomial \( H(\text{div}, \Omega) \)-conforming equilibrated flux reconstruction, in extension of the methodology developed in [42, 36, 34, 25, 26, 37, 1, 40, 13, 43, 2, 52, 18, 5] and the references therein.

4.1 Flux and potential reconstruction

Let \( P_p(\mathcal{T}_h) \), \( p \geq 0 \), stand for piecewise polynomials on the mesh \( \mathcal{T}_h \) of total degree at most \( p \); we will denote by \( \Pi_p \) the \( L^2(\Omega) \)-orthogonal projection onto \( P_p(\mathcal{T}_h) \). For vector-valued functions, the Raviart–Thomas–Nédélec mixed finite element spaces will be used; \( RTN_p(T_h) := \{ v_h \in [L^2(\Omega)]^d; v_h|_K \in RTN_p(K) \}, p \geq 0 \), with the local spaces \( RTN_p(K) := [P_p(K)]^d + \Pi_p(K) x, K \in \mathcal{T}_h \), see Brezzi and Fortin [15] or Roberts and Thomas [44].

To obtain an \( H(\text{div}, \Omega) \)-conforming flux reconstruction, we solve homogeneous local Neumann (Neumann–Dirichlet close to the boundary) problems over patches of elements \( \mathcal{T}_h \) via the mixed finite element method:

**Definition 4.1** (Equilibrated flux reconstruction). Let \( u_h \in H^1(\mathcal{T}_h) \) satisfy Assumption 2.4. For all vertices \( a \in \mathcal{V}_h \), set 

\[
\begin{align*}
V^a_h := &\{ v_h \in RTN_p(\mathcal{T}_h) \cap H(\text{div}, \omega_a); v_h \cdot n_a = 0 \text{ on } \partial \omega_a \}, \\
Q^a_h := &\{ q_h \in \Pi_p(\mathcal{T}_h); (q_h, 1)_{\omega_a} = 0 \}, \\
V^a := &\{ v_h \in RTN_p(\mathcal{T}_h) \cap H(\text{div}, \omega_a); v_h \cdot n_a = 0 \text{ on } \partial \omega_a \setminus \partial \Omega \}, \\
Q^a := &\Pi_p(\mathcal{T}_h).
\end{align*}
\]

Then prescribe \( \sigma^a_h \in V^a_h \) and \( \tau^a_h \in Q^a_h \) by solving

\[
\begin{align*}
(\sigma^a_h, v_h)_{\omega_a} - (\tau^a_h, \nabla v_h)_{\omega_a} &= - (\psi_h \Sigma \nabla u_h, v_h)_{\omega_a} & \forall v_h \in V^a_h, \\
(\nabla \sigma^a_h, q_h)_{\omega_a} &= (\psi_h \sum \nabla u_h \nabla \psi_a, q_h)_{\omega_a} & \forall q_h \in Q^a_h
\end{align*}
\] (4.1a)

and define, after extension by zero outside of \( \omega_a \),

\[
\sigma_h := \sum_{a \in \mathcal{V}_h} \sigma^a_h.
\]

To obtain an \( H^1_0(\Omega) \)-conforming potential reconstruction, we solve homogeneous local Dirichlet problems over patches of elements \( \mathcal{T}_h \) via the finite element method:

**Definition 4.2** (Potential reconstruction). Let \( u_h \in H^1(\mathcal{T}_h) \). For all vertices \( a \in \mathcal{V}_h \), set

\[
W^a_h := \Pi_{p+1}(\mathcal{T}_h) \cap H^1_0(\omega_a).
\]

Then prescribe \( s^a_h \in W^a_h \) by solving

\[
(\nabla s^a_h, \nabla \zeta_h)_{\omega_a} = (\nabla (\psi_a u_h), \nabla \zeta_h)_{\omega_a} & \forall \zeta_h \in W^a_h
\] (4.2)

and define, after extension by zero outside of \( \omega_a \),

\[
s_h := \sum_{a \in \mathcal{V}_h} s^a_h.
\]
The two above constructions yield a piecewise vector-valued polynomial \( \sigma_h \in \mathbb{RTN}_p(T_h) \cap H(\text{div}, \Omega) \) and a piecewise scalar-valued polynomial \( s_h \in \mathbb{P}_{p+1} \cap H^1_0(\Omega) \). It is easy to verify that, crucially,

\[
\nabla \sigma_h = \Pi_p f,
\]

see \([13]\) or \([32, \text{Lemma 3.5}]\). Problems (4.1) and (4.2) actually admit local minimization characterizations, see, e.g., \([32, \text{Remarks 3.7 and 3.10}]\) and \([33, \text{Corollaries 3.1 and 3.3}]\):

**Remark 4.3 (Local minimizations).** Problems (4.1) and (4.2) can be equivalently rewritten as

\[
\begin{align*}
\sigma_h &= \arg \min_{\psi_h \in \mathbb{P}_{p+1}(\Omega)} \| \psi_h \Sigma \nabla u_h + \nabla \psi_h \|_{\omega_a} \quad \forall a \in \mathcal{T}_h, \\

s_h &= \arg \min_{\zeta_h \in \mathbb{W}_a} \| \nabla (\psi_a u_h - \zeta_h) \|_{\omega_a} \quad \forall a \in \mathcal{T}_h.
\end{align*}
\]

**Remark 4.4 (Discrete and broken gradients).** One could also choose \( s_h := \arg \min_{\zeta_h \in \mathbb{W}_a} \| \nabla (\psi_a u_h - \zeta_h) \|_{\omega_a} \) instead of (4.4b). The current choice is motivated by the key property (4.7b) below which enables to prove the (local) efficiencies in Theorem 4.8.

In practice, the approximate solution \( u_h \) is a piecewise \( p \)-degree polynomial, see Assumption 4.6 below. This fixes the degree \( p \) in Definitions 4.1 and 4.2.

### 4.2 Guaranteed error control

We present here an a posteriori error estimate on the intrinsic error \( \| u - u_h \| \) given by (2.11), still merely under Assumption 2.4, in the very abstract setting \( u_h \in H^1(\mathcal{T}_h) \). Define the data oscillation estimators

\[
\eta_{osc,K} := \frac{h_K}{\pi} \| f - \Pi_p f \|_{\mathcal{K}}, \quad K \in \mathcal{T}_h.
\]

It follows as in \([32]\) and the references therein that:

**Theorem 4.5 (A posteriori estimate in a unified framework).** Let \( u \) be the weak solution of problem (1.1) given by (1.2). Let \( u_h \in H^1(\mathcal{T}_h) \) satisfying Assumption 2.4 be arbitrary. Consider the equilibrated flux reconstructions of Definition 4.1 and the potential reconstruction of Definition 4.2. Then the error \( u - u_h \) measured in intrinsic norm (2.11) can be estimated by

\[
\| u - u_h \|^2 \leq \sum_{K \in \mathcal{T}_h} \left( \| \Sigma \nabla \theta u_h + \sigma_h \|_{\mathcal{K}} + \eta_{osc,K} \right)^2 + \sum_{K \in \mathcal{T}_h} \| \nabla \theta (u_h - s_h) \|^2_{\mathcal{K}} + \sum_{e \in \mathcal{E}_h} h_e^{-1} \| \Pi_p [u_h] \|^2_{\mathcal{E}}. \tag{4.5}
\]

**Proof.** We present the proof for self-containedness. From (2.11), we need to bound \( \| u - u_h \|^2 \) and \( \| u - u_h \|^2_{\eta_a} \) separately. Using the definition of the dual norm (2.1a), the definition of the weak solution (1.2), and the consistency property (2.8), we derive

\[
\| u - u_h \|^2 = \max_{\varphi \in H^1_0(\Omega)} \frac{1}{\| \nabla \varphi \|_{\mathcal{K}}} \left( \Sigma \nabla \theta (u - u_h), \nabla \varphi \right) = \max_{\varphi \in H^1_0(\Omega)} \{ (f, \varphi) - (\Sigma \nabla \theta u_h, \nabla \varphi) \}. \tag{4.6}
\]

Next, we add and subtract \( \Pi_p f \) and employ the crucial divergence property (4.3) of our equilibrated flux reconstruction \( \sigma_h \) as well as the Green theorem \((\nabla \sigma_h, \varphi) + (\sigma_h, \nabla \varphi) = 0\), since \( \sigma_h \in H(\text{div}, \Omega) \) and \( \varphi \in H^1_0(\Omega) \). This leads to

\[
\| u - u_h \|^2 = \max_{\varphi \in H^1_0(\Omega)} \frac{1}{\| \nabla \varphi \|_{\mathcal{K}}} \left( f - \Pi_p f, \varphi - (\Sigma \nabla \theta u_h + \sigma_h, \nabla \varphi) \right)
\]

\[
= \max_{\varphi \in H^1_0(\Omega)} \sum_{K \in \mathcal{T}_h} \{ (f - \Pi_p f, \varphi - \Pi_0 \varphi) + (\Sigma \nabla \theta u_h + \sigma_h, \nabla \varphi) \}.
\]

From here, the elementwise Poincaré inequality \( \| \varphi - \Pi_0 \varphi \|_{\mathcal{K}} \leq \frac{h_K}{\pi} \| \nabla \varphi \|_{\mathcal{K}} \), cf. (3.4) (note that simplices are convex yielding the constant \( 1/\pi \)), and the Cauchy–Schwarz inequality lead to the first term of (4.5). The second and third terms of (4.5) follow immediately from the definition (2.9a) applied to \( \| u - u_h \|^2_{\eta_a} \). Indeed, using (2.13), it is enough to note that the potential reconstruction \( s_h \in H^1_0(\Omega) \), so that we can use it to bound the first term on the second line of (2.13).
4.3 Robust (local) efficiency

We now prove the converse statement to Theorem 4.5, and this locally in the neighborhood of each mesh element. Results of Section 3 are of course crucial here, stating that the intrinsic norm (2.11) in which we measure the error indeed admits a local structure. For this local efficiency result, we need to suppose that the approximate solution $u_h$ is a piecewise polynomial of the degree $p$, which fixes the polynomial degree used in Definition 4.1 and 4.2:

**Assumption 4.6 (Piecewise polynomial approximation).** The approximate solution $u_h$ is a piecewise polynomial of degree $p \geq 1$, $u_h \in \mathbb{P}_p(T_h)$.

Moreover, we henceforth also assume that the diffusion tensor $\Sigma$ is piecewise constant (possible generalizations are described below in Remark 4.10):

**Assumption 4.7 (Piecewise constant diffusion).** The diffusion tensor $\Sigma$ is piecewise constant with respect to the computational mesh $T_h$.

The crucial ingredient for local efficiency under Assumptions 4.6 and 4.7 are the following two stability results for the problems (4.1) and (4.2), shown respectively in [12, Theorem 7] and in [32, Corollary 3.16] in two space dimensions and extended to three space dimensions in [33, Corollaries 3.1 and 3.3] (recall that the space $H^1_l(\omega_a)$ is given by (3.1)):

$$\begin{align*}
\|\psi_a \Sigma \nabla u_h + \sigma_a\|_{\omega_a} &\leq C_{\text{st}} \max_{\varphi \in H^1_l(\omega_a); \|\nabla \varphi\|_{\omega_a} = 1} \left\{ -(\psi_a \Sigma \nabla u_h, \nabla \varphi)_{\omega_a} + (\Pi_p(\psi_a f) - \Sigma \nabla u_h, \nabla \psi_a, \varphi)_{\omega_a} \right\}, \\
\min_{\zeta \in W^k_0(\omega_a)} \|\nabla_b (\psi_a u_h - \zeta)\|_{\omega_a} &\leq C_{\text{st}} \min_{\zeta \in H^1_l(\omega_a)} \|\nabla_b (\psi_a u_h - \zeta)\|_{\omega_a}.
\end{align*}$$

(4.7a)

Here $C_{\text{st}}$ is a constant that only depends on the mesh shape regularity $\kappa_T$ and on the space dimension $d$. A computable upper bound on $C_{\text{st}}$ is given in [32, Lemma 3.23]. Note that (4.7b) is stated for the broken gradient (2.5).

Define a local efficiency data oscillation term

$$\bar{\eta}_{\text{osc}, K} := \frac{h_K}{\pi} \|\psi_a f - \Pi_p(\psi_a f)\|_K, \quad K \in T_h,$$

(4.8)

together with $\bar{\eta}_{\text{osc}} := \left\{ \sum_{K \in T_h} (\bar{\eta}_{\text{osc}, K})^2 \right\}^{1/2}$. Recall that the dual norm of the residual $\|u - u_h\|_*$ is defined by (2.1a) and it localizes following Proposition 3.1; the distance to the energy space $\|u - u_h\|_\#$ is given by (2.9a) and it localizes following Proposition 3.5; the broken gradient is given by (2.7) and the discrete gradient by (2.7); the constants $C_{\text{cont,PF}}, C_{\text{cont,bPF}}$, and $C_{\text{loc}}$ are respectively given by (3.2), (3.5), and (3.13). We then have:

**Theorem 4.8 (Local and global efficiency and robustness for Theorem 4.5).** Let $u$ be the weak solution given by (1.2), let $u_h$ satisfy Assumptions 2.4 and 4.6, and let Assumption 4.7 on the diffusion tensor be satisfied. Then, for $\sigma_a$ given by Definition 4.1,

$$\begin{align*}
\|\Sigma \nabla u_h + \sigma_a\|_K &\leq C_{\text{st}} C_{\text{cont,PF}} \sum_{a \in V_K} \|u - u_h\|_{\omega_a} + C_{\text{st}} \sum_{a \in V_K} \left\{ \sum_{K' \in T_a} \bar{\eta}_{\text{osc}, K'}^2 \right\}^{1/2} \quad \forall K \in T_h, \\
\|\Sigma \nabla u_h + \sigma_a\| &\leq (d + 1) C_{\text{cont,bPF}} \|u - u_h\|_\# + (d + 1) C_{\text{st}} \bar{\eta}_{\text{osc}}.
\end{align*}$$

(4.9a)

(4.9b)

Similarly, for $s_h$ given by Definition 4.2, when $\|u_h\|_1 = 0$ for all faces $e \in \mathcal{E}_h$,

$$\begin{align*}
\|\nabla_b (u_h - s_h)\|_K &\leq C_{\text{st}} C_{\text{cont,bPF}} \sum_{a \in V_K} \|u - u_h\|_{\#}, \omega_a \quad \forall K \in T_h, \\
\|\nabla_b (u_h - s_h)\| &\leq (d + 1) C_{\text{cont,bPF}} \|u - u_h\|_\#
\end{align*}$$

(4.10a)

(4.10b)

and in general

$$\begin{align*}
\|\nabla_b (u_h - s_h)\|_K &\leq C_{\text{st}} C_{\text{loc}} \sum_{a \in V_K} \sum_{a' \in \mathcal{E}_{a}} \|u - u_h\|_{\#}, \omega_a' \quad \forall K \in T_h, \\
\|\nabla_b (u_h - s_h)\| &\leq (d + 1)^{1/2} C_{\text{st}} C_{\text{loc}} \|u - u_h\|_\#.
\end{align*}$$

(4.11a)

(4.11b)
Thus (4.10a) follows. The global efficiency (4.10b) is then a consequence of the estimate of the form (3.17) that yields the potential reconstruction decomposition (4.7b) together with (3.18) and (3.23) give inequalities (4.10).

Next, the finite element stability (4.7b), inequalities (3.18)–(3.19) with \( v = u_h \), the local norm definition (2.9b), and the fact that (\( \{ u_h \} \), 1) = 0 for all \( c \in \mathcal{E} \) imply \( \| u_h \|_{\mathcal{E}, \omega_n} = \| u - u_h \|_{\mathcal{E}, \omega_n} \), proceeding as in (2.13). Thus
\[
\| \nabla_b(\psi_a u_h - s_h) \|_{\omega_n} \leq C_{st} \min_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi_a u_h - \zeta) \|_{\omega_n} \leq C_{st} C_{cont,bPF} \| u - u_h \|_{\mathcal{E}, \omega_n}.
\]

(4.14) Thus (4.10a) follows. The global efficiency (4.10b) is then a consequence of the estimate of the form (3.17) with (4.13), (4.14), (3.15b), and the norm definitions (2.9)
\[
\| \nabla_b(\psi_a u_h - s_h) \|^2 \leq (d + 1) \sum_{a \in \mathcal{V}_h} \| \nabla_b(\psi_a u_h - s_h) \|^2 \leq (d + 1) C_{st}^2 \sum_{a \in \mathcal{V}_h} \min_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi_a u_h - \zeta) \|^2 \leq (d + 1) C_{st}^2 C_{cont,bPF} \sum_{a \in \mathcal{V}_h} \| u - u_h \|^2_{\mathcal{E}, \omega_n}
\]

(4.15) In order to show (4.11a), remark that, using the discrete gradient definition (2.7), the triangle inequality, and (4.13),
\[
\| \nabla_b(\psi_a u_h - s_h) \|_K = \left\| \nabla_b(\psi_a u_h - s_h) - \theta \sum_{c \in \mathcal{E}_h} l_c(\| u_h \|) \right\|_K \leq \sum_{a \in \mathcal{V}_h} \| \nabla_b(\psi_a u_h - s_h) \|_{\omega_n} + \| \theta \| \sum_{c \in \mathcal{E}_h} l_c(\| u_h \|) \right\|_K.
\]

First, as in (3.22), employing definition (2.9b),
\[
\left\| \sum_{c \in \mathcal{E}_h} l_c(\| u_h \|) \right\|_K \leq (d + 1)^{1/2} C_{inv} \left\{ \sum_{c \in \mathcal{E}_h} h_c^{-1} \| \Pi^0_c[v] \|^2 \right\}^{1/2} \leq \frac{1}{d} (d + 1)^{1/2} C_{inv} \sum_{a \in \mathcal{V}_h} \| u - u_h \|_{\mathcal{E}, \omega_n}.
\]

Next, the finite element stability (4.7b) together with (3.18) and (3.23) give
\[
\| \nabla_b(\psi_a u_h - s_h) \|_{\omega_n} \leq C_{st} \min_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi_a u_h - \zeta) \|_{\omega_n} \leq C_{st} \inf_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi_a u_h - \zeta) \|_{\omega_n}
\]

Using once more the discrete gradient definition (2.7) and proceeding as in (3.24),
\[
\min_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi_a u_h - \zeta) \|^2 \leq 2 \min_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi_a u_h - \zeta) \|^2 + 2 \| \theta \|^2 \sum_{c \in \mathcal{E}_h, a \in \mathcal{E}} l_c(\| u_h \|) \right\|_{\omega_n} \leq 2 \min_{\zeta \in H^1_0(\omega)} \| \nabla_b(\psi_a u_h - \zeta) \|^2 + 2 \| \theta \|^2 (d + 1) C_{inv} \sum_{c \in \mathcal{E}_h, a \in \mathcal{E}} h_c^{-1} \| \Pi^0_c[u_h] \|^2 \leq \left( 2 + \frac{1}{d} 2 \| \theta \|^2 (d + 1) C_{inv} \right) \sum_{a \in \mathcal{E}_h} \| u - u_h \|^2_{\mathcal{E}, \omega_n}.
\]
where we have used estimate of the form (3.22) for such faces $e \in E_h$ that lie in the closure of the patch subdomain $\omega_{a'}'$, whence
\[
\min_{\zeta \in H^1_0(\omega_{a'})} \| \nabla_b(u_h - \zeta) \|_{\omega_a} \leq \left( 2 + \frac{1}{d} 2^2 |\theta|^2 (d + 1) C_{\text{inv}}^2 \right)^{1/2} \sum_{a' \in \Sigma} u - u_h \|_{\# \omega_{a'}}.
\]
Altogether,
\[
\| \nabla \theta(u_h - s_h) \|_K \leq C_{st} C_{\text{cont,PF}} \left( 2 + \frac{1}{d} 2^2 |\theta|^2 (d + 1) C_{\text{inv}}^2 \right)^{1/2} \sum_{a \in V_K} a' \in \Sigma \sum_{a' \in \Sigma} u - u_h \|_{\# \omega_{a'}}
\]
\[
+ C_{st} C_{\text{cont,PF}} \sum_{a \in V_K} \| u - u_h \|_{\# \omega_a}
\]
\[
+ \frac{1}{d} |\theta|(d + 1)^{1/2} C_{\text{inv}} \sum_{a \in V_K} \| u - u_h \|_{\# \omega_a},
\]
which proves (4.11a), using that $C_{st} \geq 1$ and definition (3.13) of the constant $C_{\text{loc}}$.

Finally, for the global bound (4.11b), we first use, as in (3.21)–(3.22),
\[
\| \nabla \theta(u_h - s_h) \|_e^2 \leq 2 \| \nabla_b(u_h - s_h) \|^2 + 2 |\theta|^2 (d + 1) C_{\text{inv}}^2 \sum_{e \in E_h} h_e^{-1} \| \Pi^0 u_h \|^2.
\]
One next employs the first line of (4.15). From there, the conclusion follows as in the proof of Proposition 3.5. \hfill $\square$

**Remark 4.9** (Efficiency in the $L^2$ flux norm for Theorem 4.8). The Cauchy–Schwarz inequality gives $\| v \|_{*; \omega_a} \leq \| \Sigma \nabla \theta v \|_{\omega_a}$ and $\| v \|_{*} \leq \| \Sigma \nabla \theta v \|$ for all $v \in H^1(T_h)$ from (2.1), so that, immediately,
\[
\| \Sigma \nabla \theta u_h + \sigma_h \|_K \leq C_{st} C_{\text{cont,PF}} \sum_{a \in V_K} \| \Sigma \nabla \theta(u - u_h) \|_{\omega_a} + C_{st} \sum_{a \in V_K} \left\{ \sum_{K' \in T_a} \frac{1}{a} \| \Pi^0 u_h \|_{\# \omega_{K'}} \right\}^{1/2} \forall K \in T_h,
\]
\[
\| \Sigma \nabla \theta u_h + \sigma_h \| \leq (d + 1) C_{st} C_{\text{cont,PF}} \| \Sigma \nabla \theta(u - u_h) \| + (d + 1) C_{st} \| \Pi^0 u_h \|_{\# \omega_a}.
\]

Applications to conforming, nonconforming, mixed, and discontinuous Galerkin approximations are straightforward following [32, Section 4].

**Remark 4.10** (More general diffusion tensors $\Sigma$). For Theorem 4.8, the requirement of piecewise constant diffusion tensor $\Sigma$ from Assumption 4.6 is unavoidable. It is namely crucial for inequality (4.7a) to hold. If $\Sigma$ is piecewise polynomial of degree $p$ and $u_h$ is piecewise polynomial of degree $p$, then $\text{RTN}_{p+p'}(T_h)$ spaces would need to be chosen in Definition 4.1 to maintain the present form of the results; otherwise a supplementary oscillation term of the datum $\Sigma$ of the form of (4.8) would appear in Theorem 4.8.

**Remark 4.11** (Polynomial degree and cost of the reconstructions). The reconstruction of Definition 4.1 relies on solution of local problems with $\text{RTN}_{p}(T_h)$-spaces, whereas that of Definition 4.2 on solution of local problems with $\mathbb{P}_{p+1}(T_h)$ spaces. Although these constructions are local, the associated computational burden may not be completely negligible. There exist various ways how to decrease it. First, the proofs in [12] and [33] actually show that the solves of local problems on each patch $T_h$ by finite elements can be replaced by an explicit run through $T_h$ and a local construction inside each mesh element. This explicit construction remarkably maintains the polynomial-degree robustness. Equilibrated reconstruction in $\text{RTN}_{p-1}(T_h)$ for $u_h \in \mathbb{P}_p$ has also been suggested in [12] and analyzed in [31, Section 6.2]; one does not know here, however, whether it leads to polynomial-degree robustness. A recent survey of cheaper (but possibly not polynomial-degree robust) a posteriori estimators via reconstructions can be found in [5].

## 5 Numerical experiments

We report here the results of two numerical experiments, while relying on the conforming piecewise affine finite element approximation: find $u_h \in V_h := \mathbb{P}_1(T_h) \cap H^1_0(\Omega)$ such that
\[
(\Sigma \nabla u_h, \nabla v_h) = (f, v_h) \quad \forall v_h \in V_h.
\]
Figure 1: Exact (left) and approximate (right) solution with the corresponding initial mesh, the regular case with $\sigma_- = -1/3$

The experiments were implemented by Jan Blechta (Charles University, Prague) using the dolfin-tape [7] package built on top of the FEniCS Project [3].

We start by noting that since $u_h \in H^1_0(\Omega)$, $\|u - u_h\| = \|u - u_h\|_*$ and the nonconformity error $\|u - u_h\|_\# = 0$. We will focus on our a posteriori error estimates of Theorem 4.5, while tracing the error $\|u - u_h\|_*$ defined by (2.1a) and the estimate of (4.5) that simplifies to

$$\|u - u_h\|_* \leq \eta := \left\{ \sum_{K \in T_h} (\|\Sigma \nabla u_h + \sigma_h\|_{K} + \eta_{osc.K})^2 \right\}^{1/2};$$  \hfill (5.2)

indeed, $s_h = u_h$ and $[u_h] = 0$ for all $e \in \mathcal{E}_h$ here, cf. (4.11). The efficiency of our estimates, proven by (4.9b) of Theorem 4.8, is in practice best appreciated by the effectivity index

$$\text{Eff} := \frac{\eta}{\|u - u_h\|_*}. \hfill (5.3)$$

Note in this respect that $\|u - u_h\|_*$ cannot easily be computed even if $u$ is known, as this will be the case below. Indeed, from (2.1a) and (1.2), see (4.6), $\|u - u_h\| = \|\nabla \mathfrak{r}\|$, where $\mathfrak{r}$ is the Riesz representer of the residual, $\mathfrak{r} \in H^1_0(\Omega)$ such that

$$(\nabla \mathfrak{r}, \nabla v) = (f, v) - (\Sigma \nabla u_h, \nabla v) \quad \forall v \in H^1_0(\Omega). \hfill (5.4)$$

In what follows, we compute $\|u - u_h\|_*$ approximately, while approximating (5.4). We again employ a posteriori error estimates to ensure that $\|u - u_h\|_*$ is computed with relative accuracy $10^{-2}$, see the details in [8, Section 5]. We will also display the canonical $H^1_0(\Omega)$-norm of the error $\|\nabla (u - u_h)\|$.

Two test cases, one with a regular solution and one with a singular solution, are considered. Only uniform mesh refinement is used in the first case, whereas mesh adaptivity is employed in the second one. Here all elements where the estimator exceeds 50$\%$ of the maximal estimator value on the given mesh are refined by the so-called newest-vertex bisection refinement algorithm.

### 5.1 A regular weak solution

We first consider the test case from [39, Section 5.1] with a regular solution. We set $\Omega := (-1, 1) \times (-1, 1)$ with $\Omega_+ := (0, 1) \times (-1, 1)$ and $\Omega_- := (-1, 0) \times (-1, 1)$ and let $\Sigma|_{\Omega_+} = \sigma_+ \mathbf{I}$, $\Sigma|_{\Omega_-} = \sigma_- \mathbf{I}$ with $\sigma_+ = 1$ and $\sigma_- < 0$. The exact solution is given by

$$u(x, y) = \sigma_- x(x + 1)(x - 1)(y + 1)(y - 1) \quad \text{for} \ (x, y) \in \Omega_+,$$

$$u(x, y) = x(x + 1)(x - 1)(y + 1)(y - 1) \quad \text{for} \ (x, y) \in \Omega_-,$$
and the (inhomogeneous) source term $f$ is prescribed accordingly. Note that this solution indeed leads to the homogeneous Dirichlet boundary condition. Together with its finite element approximation and the corresponding initial mesh for the setting $\sigma_- = -1/3$, it is presented in Figure 1. Higher values of the approximate solution can be noted in particular in the left subdomain $\Omega_-$. Specifying the operator $T$ as in [39], see also Remark 5.1 below, one can see that the problem is well-posed when $\sigma_- \neq -1$.

The $\|u - u_h\|_*$ and $\|\nabla (u - u_h)\|$ errors and the estimate $\eta$ of (5.2) are traced in the left parts of Figures 2–4, for three different choices of the parameter $\sigma_-$. The corresponding effectivity indices given by (5.3) are plotted in the right parts of these figures. We observe a systematic first-order decrease of both errors, as predicted by the a priori error analysis, cf. [20]. The overall estimator $\eta$ of (5.2), as well as its principal component given by $\{\sum_{K \in T_h} \|\Sigma \nabla u_h + \sigma_K\|^2\}^{1/2}$, also decrease with first order, in agreement with Theorems 4.5 and 4.8. On the other hand, the data oscillation estimator $\{\sum_{K \in T_h} \eta_{osc,K}^2\}^{1/2}$ decreases with a slope of two and its influence rapidly diminishes.

The effectivity indices in all the three settings are very close to the optimal value of one, including the last challenging case $\sigma_- = -0.99$ which is very close to the well-posedness limit. This clearly demonstrates the robustness of our estimates with respect to the jump and sign-change in the diffusion tensor $\Sigma$, if the error is measured in the intrinsic norm $\|u - u_h\|_*$. It can be noted from Figures 2–4 that such a robustness does not hold for the canonical norm $\|\nabla (u - u_h)\|$. Similarly, the upper bound $\|\Sigma \nabla (u - u_h)\|$ and the lower bound $\|\Sigma \nabla (u - u_h), \Sigma(T(u - u_h))\|/\|\nabla (1(u - u_h))\|$ on the intrinsic error $\|u - u_h\|_*$, given by (2.2) seem rather $\Sigma$- and $T$-dependent, see in particular the numerical study in [22, Section 6]. Finally, Figure 5 illustrates that the distribution of the error is predicted very correctly by our estimators (plotting by a piecewise affine function is done as explained in [8, Section 5]).

We finish this section by a remark relative to the specific case $\sigma_- = -1/3$:

**Remark 5.1 (Equivalence of the intrinsic norm with its upper and lower bounds).** Consider the intrinsic

Figure 2: Estimates and errors for uniform mesh refinement (left) and the corresponding effectivity indices (right), the regular case with $\sigma_- = -0.01$
norm \(\|u - u_h\|\) given by (2.1a) together with its upper \(\|\Sigma \nabla (u - u_h)\|\) and lower bounds \(\frac{\|\Sigma \nabla (u - u_h)\|}{\|\nabla (u - u_h)\|}\) that follow from (2.2). Interestingly enough, they all coincide in the case \(\sigma_- = -1/3\). To explain this behavior, note first that \(\|\Sigma \nabla (u - u_h)\|\) and \(\|u - u_h\|\), will coincide whenever \(\Sigma \nabla (u - u_h)\) is a gradient of some scalar field from \(H^1_0(\Omega)\). This will happen when curl of \(\Sigma \nabla (u - u_h)\) = 0 on all \(K \in \mathcal{T}_h\) and \(\text{curl } \Sigma \nabla (u - u_h) = 0\) on all \(e \in E_h\). These conditions are actually satisfied in this test case for all values of \(\sigma_-\). To account for the other equality, one then notices that, when \(\sigma_- \in (-1, 0)\), the operator \(T\) may be defined as

\[
T u(x, y) = \begin{cases} 
  u_+(x, y) & \text{for } (x, y) \in \Omega_+, \\
  -u_-(x, y) + 2u_+(-x, y) & \text{for } (x, y) \in \Omega_-
\end{cases}
\]

for this test case, with \(u_+ := u|_{\Omega_+}\) and \(u_- := u|_{\Omega_-}\). The chosen exact solution being such that \(u_+(x, y) = -\sigma_- u_-(x, y)\) for \((x, y) \in \Omega_+,\) the formula for \(T u\) in \(\Omega_-\) simplifies to \((T u)|_{\Omega_-} = (-1 - 2\sigma_-)u_-\). With the help of these expressions, one may compute exactly

\[
R(\sigma_-) := \frac{\|\Sigma \nabla u, \nabla (Tu)\|}{\|\nabla (Tu)\|} = \frac{1 + 2\sigma_- + |\sigma_-|}{(1 + 2\sigma_-^2 + |\sigma_-|^2)^{1/2}} \sqrt{2}.
\]

For \(\sigma_- \in (-1/3, 0)\), it holds that \(R(\sigma_-) \in (1/\sqrt{2}, 1)\) and moreover \(R(-1/3) = 1\), whereas \(\lim_{\sigma_- \to -1} R(\sigma_-) = 0\). To obtain the same result for the ratio \(\frac{\|\Sigma \nabla (u - u_h), \nabla (T(u - u_h))\|}{\|\nabla (u - u_h)\|}\), one needs to work with symmetric meshes with respect to the line \(\{x = 0\}\), that is, globally \(T\)-conform meshes in the sense of [20]. In this case, one has \(TV_h = V_h\), so that the properties of \(T\) at the continuous level carry over to the discrete level, whereas \(u_h|_{\Omega_+}(x, y) = -\sigma_- u_h|_{\Omega_-}(-x, y)\) for \((x, y) \in \Omega_+,\) by direct inspection of the formulation (5.1).
### 5.2 A singular weak solution

We next consider the test case from [39, Section 5.2] with a singular solution. We set \( \Omega := (-1,1) \times (-1,1) \) with \( \Omega_+ := (0,1) \times (0,1) \) and \( \Omega_- := \Omega \setminus \Omega_+ \) and let again \( \Sigma|_{\Omega_+} = \sigma_+ I \), \( \Sigma|_{\Omega_-} = \sigma_- I \) with \( \sigma_+ = 1 \) and
We consider two test settings with \( \sigma \neq 0 \); consequently, the data oscillation estimators bounds, see \([28, \text{Theorems 3.3 and 3.12}]\) and \([33, \text{Corollary 3.8}]\). The source term \( f \) but we neglect here the additional quadrature estimator that theoretically appears in the upper and lower according to (5.5). It is naturally treated in the reconstruction of Definition 4.1, see \([28, \text{Definition 3.5}]\), be seen from the right part of Figure 6. The inhomogeneous Dirichlet boundary condition is prescribed steep gradient around the origin of the exact solution is largely missed by the approximation, as it can approximation on the coarsest mesh for the case \( \sigma \approx 0 \); the problem is in particular well-posed when \( \sigma \eta = 0 \), the singular case with Figure 6: Approximate solution \( u_h \) (left) the pointwise error \( u - u_h \) (right) on the corresponding initial mesh, the singular case with \( \sigma_\ell = -3.1 \)

\[
\begin{align*}
\sigma_\ell < 0. \text{ The exact solution is according to Bonnet-BenDhia et al. [11] given by} \\
u(x, y) &= r^\lambda(c_1 \sin(\lambda \theta) + c_2 \sin(\lambda(\pi/2 - \theta))) \text{ for } (x, y) \in \Omega_+,
\end{align*}
\]

\[
\begin{align*}
u(x, y) &= r^\lambda(d_1 \sin(\lambda(\theta - \pi/2)) + d_2 \sin(\lambda(2\pi - \theta))) \text{ for } (x, y) \in \Omega_-.
\end{align*}
\]

Here \((r, \theta)\) are the polar coordinates centered at the origin and \( \lambda = 2/\pi \arccos((1 - \sigma_\ell)/(2|1 + \sigma_\ell|)) \). We consider two test settings with \( \sigma_\ell = -5 \) and \( \sigma_\ell = -3.1 \) leading respectively to \( c_1 = 1, c_2 = -1, d_1 = -0.8, d_2 = -0.8, \lambda \approx 0.4601069123 \) and \( c_1 = 1, c_2 = -1, d_1 \approx -0.3556451613, d_2 \approx 0.3556451613, \lambda \approx 0.1391989493 \). Classically, \( u \in H^{1+\lambda}(\Omega) \) only, with a singularity at the origin. The finite element approximation on the coarsest mesh for the case \( \sigma_\ell = -3.1 \) is presented in the left part of Figure 6. The steep gradient around the origin of the exact solution is largely missed by the approximation, as it can be seen from the right part of Figure 6. The inhomogeneous Dirichlet boundary condition is prescribed according to (5.5). It is naturally treated in the reconstruction of Definition 4.1, see \([28, \text{Definition 3.5}]\), but we neglect here the additional quadrature estimator that theoretically appears in the upper and lower bounds, see \([28, \text{Theorems 3.3 and 3.12}]\) and \([33, \text{Corollary 3.8}]\). The source term \( f \) corresponding to (5.5) is equal to 0; consequently, the data oscillation estimators \( \eta_{osc,K} \) in (5.2) vanish. The operator \( T \) is specified in \([39] \); the problem is in particular well-posed when \( \sigma_\ell < -3 \) or \( -1/3 < \sigma_\ell < 0 \).

The intrinsic error norm \( \|u - u_h\|_x \) together with the canonical error norm \( \|\nabla (u - u_h)\| \) and the estimator \( \eta \) given by (5.2) are presented in the left parts of Figures 7–8. The corresponding effectivity indices are then given in the right parts of these figures. They are remarkably close to the optimal value of one in all the settings, illustrating numerically the robustness that has been proven in Section 4. The convergence orders of both errors and of the estimate for uniform mesh refinement correspond to the a priori analysis, being 0.46 and 0.12 respectively in the two settings. For adaptive mesh refinement (after a preliminary phase for the strongly singular setting), the convergence orders are optimal and close to 1. Finally, the predicted spatial distribution of the error still seems to be very accurate even in the close-to-the-limit singular case \( \sigma_\ell = -3.1 \), see Figure 9.

### 6 Conclusions and outlook

We have shown in this work that globally defined dual norms as well as globally defined distance norms to the energy space admit an equivalent localization. Direct proofs with clearly identified constants are given. In the setting of the transmission problem with sign-changing coefficients (1.1), this suggests that the intrinsic global norm (2.11) is suitable for a posteriori error analysis. Indeed, relying on the concept of flux and potential reconstructions, we have obtained a guaranteed upper bound, as well as local lower bounds up to a generic constant independent of the jump or sign change in the diffusion coefficient and the approximation
polynomial degree. This robustness is moreover obtained in a unified framework covering basically all classical numerical methods. Numerical experiments, in the conforming finite element setting, confirm these results. Possible future developments include control of the error from a not completely converged linear solver (and corresponding stopping criteria), extension to nonlinear problems, or proposition of an adaptive operator T for self-adapting the method.

### A Localization of the flux distance to the energy space

In extension of the discussion in Section 2.7, we can observe that

\[ \|u - u_h\| \leq \min_{\sigma \in \mathbf{H}(\text{div}; \Omega), \nabla \sigma = f} \| \sum \nabla \sigma u_h + \sigma \| \]

by the Green theorem, so that \( \|u - u_h\| \) is linked to the nonconformity in the approximate flux \( -\sum \nabla \sigma u_h \).

We now present for this term a localization result like those of Section 3.2. Let \( \mathbf{H}(\text{div}; \omega_a) \) stand for \( \mathbf{H}(\text{div}; \omega_a) \) functions with zero normal trace in the appropriate sense on \( \partial \omega_a \) for \( a \in V^\text{int}_h \) and for \( \mathbf{H}(\text{div}; \omega_a) \) functions with zero normal trace in the appropriate sense on \( \partial \omega_a \setminus \partial \Omega \) for \( a \in V^\text{ext}_h \). One can show similarly as in Section 3.2, with the constant \( C_{\text{cont},PF} \) of inequality (3.2) that:

**Theorem A.1** (Localization of the flux nonconformity evaluation). Let \( u_h \in H^1(T_h) \) satisfying Assumption 2.4 be arbitrary. Then

\[
\min_{\sigma \in \mathbf{H}(\text{div}; \Omega), \nabla \sigma = f} \| \sum \nabla \sigma u_h + \sigma \|^2 \leq (d + 1) \sum_{a \in V_h} \min_{\sigma^a \in \mathbf{H}(\text{div}; \omega_a), \nabla \sigma^a = \psi_a f - \sum \nabla \sigma u_h, \nabla \psi_a} \| \psi_a \sum \nabla \sigma u_h + \sigma^a \|^2_{\omega_a},
\]

\[
\sum_{a \in V_h} \min_{\sigma^a \in \mathbf{H}(\text{div}; \omega_a), \nabla \sigma^a = \psi_a f - \sum \nabla \sigma u_h, \nabla \psi_a} \| \psi_a \sum \nabla \sigma u_h + \sigma^a \|^2_{\omega_a} \leq (d + 1) C_{\text{cont},PF}^2 \min_{\sigma \in \mathbf{H}(\text{div}; \Omega), \nabla \sigma = f} \| \sum \nabla \sigma u_h + \sigma \|^2.
\]
